The Little Schemer

Fourth Edition

Daniel P. Friedman and Matthias Felleisen

Foreword by Gerald J. Sussman
The Ten Commandments

The First Commandment
When recurring on a list of atoms, \( \text{lat} \), ask two questions about it: \((\text{null? } \text{lat})\) and \text{else}. When recurring on a number, \( \text{n} \), ask two questions about it: \((\text{zero? } \text{n})\) and \text{else}. When recurring on a list of S-expressions, \( \text{l} \), ask three questions about it: \((\text{null? } \text{l})\), \((\text{atom? } \text{car } \text{l})\), and \text{else}.

The Second Commandment
Use \text{cons} to build lists.

The Third Commandment
When building a list, describe the first typical element, and then \text{cons} it onto the natural recursion.

The Fourth Commandment
Always change at least one argument while recurring. When recurring on a list of atoms, \( \text{lat} \), use \((\text{cdr } \text{lat})\). When recurring on a number, \( \text{n} \), use \((\text{sub1 } \text{n})\). And when recurring on a list of S-expressions, \( \text{l} \), use \((\text{car } \text{l})\) and \((\text{cdr } \text{l})\) if neither \((\text{null? } \text{l})\) nor \((\text{atom? } \text{car } \text{l})\) are true.

It must be changed to be closer to termination. The changing argument must be tested in the termination condition:
when using \text{cdr}, test termination with \text{null?} and
when using \text{sub1}, test termination with \text{zero?}.

The Fifth Commandment
When building a value with \( + \), always use 0 for the value of the terminating line, for adding 0 does not change the value of an addition.

When building a value with \( \times \), always use 1 for the value of the terminating line, for multiplying by 1 does not change the value of a multiplication.

When building a value with \text{cons}, always consider () for the value of the terminating line.

The Sixth Commandment
Simplify only after the function is correct.

The Seventh Commandment
Recur on the subparts that are of the same nature:
• On the sublists of a list.
• On the subexpressions of an arithmetic expression.

The Eighth Commandment
Use help functions to abstract from representations.

The Ninth Commandment
Abstract common patterns with a new function.

The Tenth Commandment
Build functions to collect more than one value at a time.
The Five Rules

The Law of Car

The primitive \texttt{car} is defined only for non-empty lists.

The Law of Cdr

The primitive \texttt{cdr} is defined only for non-empty lists. The \texttt{cdr} of any non-empty list is always another list.

The Law of Cons

The primitive \texttt{cons} takes two arguments. The second argument to \texttt{cons} must be a list. The result is a list.

The Law of Null?

The primitive \texttt{null?} is defined only for lists.

The Law of Eq?

The primitive \texttt{eq?} takes two arguments. Each must be a non-numeric atom.

Foreword

This foreword appeared in the second and third editions of *The Little LISPer*. We reprint it here with the permission of the author.

In 1967 I took an introductory course in photography. Most of the students (including me) came into that course hoping to learn how to be creative—to take pictures like the ones I admired by artists such as Edward Weston. On the first day the teacher patiently explained the long list of technical skills that he was going to teach us during the term. A key was Ansel Adams’ “Zone System” for previsualizing the print values (blackness in the final print) in a photograph and how they derive from the light intensities in the scene. In support of this skill we had to learn the use of exposure meters to measure light intensities and the use of exposure time and development time to control the black level and the contrast in the image. This is in turn supported by even lower level skills such as loading film, developing and printing, and mixing chemicals. One must learn to ritualize the process of developing sensitive material so that one gets consistent results over many years of work. The first laboratory session was devoted to finding out that developer feels slippery and that fixer smells awful.

But what about creative composition? In order to be creative one must first gain control of the medium. One can not even begin to think about organizing a great photograph without having the skills to make it happen. In engineering, as in other creative arts, we must learn to do analysis to support our efforts in synthesis. One cannot build a beautiful and functional bridge without a knowledge of steel and dirt and considerable mathematical technique for using this knowledge to compute the properties of structures. Similarly, one cannot build a beautiful computer system without a deep understanding of how to “previsualize” the process generated by the procedures one writes.

Some photographers choose to use black-and-white 8×10 plates while others choose 35mm slides. Each has its advantages and disadvantages. Like photography, programming requires a choice of medium. Lisp is the medium of choice for people who enjoy free style and flexibility. Lisp was initially conceived as a theoretical vehicle for recursion theory and for symbolic algebra. It has developed into a uniquely powerful and flexible family of software development tools, providing wrap-around support for the rapid-prototyping of software systems. As with other languages, Lisp provides the glue for using a vast library of canned parts, produced by members of the user community. In Lisp, procedures are first-class data, to be passed as arguments, returned as values, and stored in data structures. This flexibility is valuable, but most importantly, it provides mechanisms for formalizing, naming, and saving the idioms—the common patterns of usage that are essential to engineering design. In addition, Lisp programs can easily manipulate the representations of Lisp programs—a feature that has encouraged the development of a vast structure of program synthesis and analysis tools, such as cross-referencers.

*The Little LISPer* is a unique approach to developing the skills underlying creative programming in Lisp. It painlessly packages, with considerable wit, much of the drill and practice that is necessary to learn the skills of constructing recursive processes and manipulating recursive data-structures. For the student of Lisp programming, *The Little LISPer* can perform the same service that Hanon’s finger exercises or Czerny’s piano studies perform for the student of piano.

Gerald J. Sussman
Cambridge, Massachusetts
Preface

To celebrate the twentieth anniversary of Scheme we revised The Little LISPer a third time, gave it the more accurate title The Little Schemer, and wrote a sequel: The Seasoned Schemer.

Programs accept data and produce data. Designing a program requires a thorough understanding of data; a good program reflects the shape of the data it deals with. Most collections of data, and hence most programs, are recursive. Recursion is the act of defining an object or solving a problem in terms of itself.

The goal of this book is to teach the reader to think recursively. Our first task is to decide which language to use to communicate this concept. There are three obvious choices: a natural language, such as English; formal mathematics; or a programming language. Natural languages are ambiguous, imprecise, and sometimes awkwardly verbose. These are all virtues for general communication, but something of a drawback for communicating concisely as precise a concept as recursion. The language of mathematics is the opposite of natural language: it can express powerful formal ideas with only a few symbols. Unfortunately, the language of mathematics is often cryptic and barely accessible without special training. The marriage of technology and mathematics presents us with a third, almost ideal choice: a programming language. We believe that programming languages are the best way to convey the concept of recursion. They share with mathematics the ability to give a formal meaning to a set of symbols. But unlike mathematics, programming languages can be directly experienced—you can take the programs in this book, observe their behavior, modify them, and experience the effect of these modifications.

Perhaps the best programming language for teaching recursion is Scheme. Scheme is inherently symbolic—the programmer does not have to think about the relationship between the symbols of his own language and the representations in the computer. Recursion is Scheme's natural computational mechanism; the primary programming activity is the creation of (potentially) recursive definitions. Scheme implementations are predominantly interactive—the programmer can immediately participate in and observe the behavior of his programs. And, perhaps most importantly for our lessons at the end of this book, there is a direct correspondence between the structure of Scheme programs and the data those programs manipulate.

Although Scheme can be described quite formally, understanding Scheme does not require a particularly mathematical inclination. In fact, The Little Schemer is based on lecture notes from a two-week “quickie” introduction to Scheme for students with no previous programming experience and an admitted dislike for anything mathematical. Many of these students were preparing for careers in public affairs. It is our belief that writing programs recursively in Scheme is essentially simple pattern recognition. Since our only concern is recursive programming, our treatment is limited to the whys and wherefores of just a few Scheme features: car, cdr, cons, eq?, null?, zero?, add1, sub1, number?, and, or, quote, lambda, define, and cond. Indeed, our language is an idealized Scheme.

The Little Schemer and The Seasoned Schemer will not introduce you to the practical world of programming, but a mastery of the concepts in these books provides a start toward understanding the nature of computation.
What You Need to Know to Read This Book

The reader must be comfortable reading English, recognizing numbers, and counting.

Acknowledgments

We are indebted to many people for their contributions and assistance throughout the development of the second and third editions of this book. We thank Bruce Duba, Kent Dybvig, Chris Haynes, Eugene Kohlb Becker, Richard Salter, George Springer, Mitch Wand, and David S. Wise for countless discussions that influenced our thinking while conceiving this book. Ghassan Abbas, Charles Baker, David Boyer, Mike Dunn, Terry Falkenberg, Rob Friedman, John Gateley, Mayer Goldberg, Iqbal Khan, Julia Lawall, Jon Mendelsohn, John Nienart, Jeffrey D. Perotti, Ed Robertson, Anne Shpuntoff, Erich Smythe, Guy Steele, Todd Stein, and Larry Weisselberg provided many important comments on the drafts of the book. We especially want to thank Bob Filman for being such a thorough and uncompromising critic through several readings. Finally we wish to acknowledge Nancy Garrett, Peg Fletcher, and Bob Filman for contributing to the design and \TeX{}ery.

The fourth and latest edition greatly benefited from Dorai Sitaram's incredibly clever Scheme typesetting program \LaTeX{}. Kent Dybvig's Chez Scheme made programming in Scheme a most pleasant experience. We gratefully acknowledge criticisms and suggestions from Shelaswau Bushnell, Richard Cobbe, David Combs, Peter Drake, Kent Dybvig, Rob Friedman, Steve Ganz, Chris Haynes, Erik Hilsdale, Eugene Kohlb Becker, Shriram Krishnamurthi, Julia Lawall, Suzanne Menzel Collin McCurdy, John Nienart, Jon Rossie, Jonathan Sobel, George Springer, Guy Steele, John David Stone, Vikram Subramaniam, Mitch Wand, and Melissa Wingard-Phillips.

Guidelines for the Reader

Do not rush through this book. Read carefully; valuable hints are scattered throughout the text. Do not read the book in fewer than three sittings. Read systematically. If you do not fully understand one chapter, you will understand the next one even less. The questions are ordered by increasing difficulty; it will be hard to answer later ones if you cannot solve the earlier ones.

The book is a dialogue between you and us about interesting examples of Scheme programs. If you can, try the examples while you read. Schemes are readily available. While there are minor syntactic variations between different implementations of Scheme (primarily the spelling of particular names and the domain of specific functions), Scheme is basically the same throughout the world. To work with Scheme, you will need to define \texttt{atom?}, \texttt{sub1}, and \texttt{add1}, which we introduced in \textit{The Little Schemeer}:

\begin{verbatim}
(define atom? \\
  (lambda (x) \\
    (and (not (pair? x)) (not (null? x)))))
\end{verbatim}

To find out whether your Scheme has the correct definition of \texttt{atom?}, try \texttt{(atom? (quote ())}) and make sure it returns \texttt{#f}. In fact, the material is also suited for modern Lisps such as Common Lisp. To work with Lisp, you will also have to add the function \texttt{atom?}:

\begin{verbatim}
(defun atom? (x) \\
  (not (listp x)))
\end{verbatim}
Moreover, you may need to modify the programs slightly. Typically, the material requires only a few changes. Suggestions about how to try the programs in the book are provided in the framenotes. Framenotes preceded by “S:” concern Scheme, those by “L:” concern Common Lisp.

In chapter 4 we develop basic arithmetic from three operators: \texttt{add1}, \texttt{sub1}, and \texttt{zero?}. Since Scheme does not provide \texttt{add1} and \texttt{sub1}, you must define them using the built-in primitives for addition and subtraction. Therefore, to avoid a circularity, our basic arithmetic addition and subtraction must be written using different symbols: \texttt{+} and \texttt{-}, respectively.

We do not give any formal definitions in this book. We believe that you can form your own definitions and will thus remember them and understand them better than if we had written each one for you. But be sure you know and understand the \textit{Laws} and \textit{Commandments} thoroughly before passing them by. The key to learning Scheme is “pattern recognition.” The \textit{Commandments} point out the patterns that you will have already seen. Early in the book, some concepts are narrowed for simplicity; later, they are expanded and qualified. You should also know that, while everything in the book is Scheme, Scheme itself is more general and incorporates more than we could intelligibly cover in an introductory text. After you have mastered this book, you can read and understand more advanced and comprehensive books on Scheme.

We use a few notational conventions throughout the text, primarily changes in typeface for different classes of symbols. Variables and the names of primitive operations are in \textit{italic}. Basic data, including numbers and representations of truth and falsehood, is set in \textsc{sans serif}. Keywords, i.e., \texttt{define}, \texttt{lambda}, \texttt{cond}, \texttt{else}, \texttt{and}, \texttt{or}, and \texttt{quote}, are in \textbf{boldface}. When you try the programs, you may ignore the typefaces but not the related framenotes. To highlight this role of typefaces, the programs in framenotes are set in a \texttt{typewriter} face. The typeface distinctions can be safely ignored until chapter 10, where we treat programs as data.

Finally, Webster defines “punctuation” as the act of punctuating; specifically, the act, practice, or system of using standardized marks in writing and printing to separate sentences or sentence elements or to make the meaning clearer. We have taken this definition literally and have abandoned some familiar uses of punctuation in order to make the meaning clearer. Specifically, we have dropped the use of punctuation in the left-hand column whenever the item that precedes such punctuation is a term in our programming language.

Food appears in many of our examples for two reasons. First, food is easier to visualize than abstract symbols. (This is not a good book to read while dieting.) We hope the choice of food will help you understand the examples and concepts we use. Second, we want to provide you with a little distraction. We know how frustrating the subject matter can be, and a little distraction will help you keep your sanity.

You are now ready to start. Good luck! We hope you will enjoy the challenges waiting for you on the following pages.

Bon appétit!

1 L: nil

The Law of Car
The primitive car is defined only for non-empty lists.
What is the *car* of \(l\) where
\[ l \) is (((hotdogs)) (and) (pickle) relish)\]

\(((\text{hotdogs}))\), read as:
"The list of the list of hotdogs."
\(((\text{hotdogs}))\) is the first S-expression of \(l\).

What is \((\text{car} \ l)\) where
\[ l \) is (((hotdogs)) (and) (pickle) relish)\]

\(((\text{hotdogs}))\), because \((\text{car} \ l)\) is another way to ask for "the car of the list \(l\)."

What is \((\text{car} (\text{car} \ l))\) where
\[ l \) is (((hotdogs)) (and))\]

\((\text{hotdogs})\).

What is the \(cdr\) of \(l\) where
\[ l \) is (a b c)\]

\((b \ c)\), because \((b \ c)\) is the list \(l\) without \((\text{car} \ l)\).

Note: "\(cdr\)" is pronounced "could-er."

What is the \(cdr\) of \(l\) where
\[ l \) is ((a b c) x y z)\]

\((x \ y \ z)\).

What is the \(cdr\) of \(l\) where
\[ l \) is (hamburger)\]

\(()\).

What is \((\text{cdr} \ l)\) where
\[ l \) is ((x) t r)\]

\((t \ r)\), because \((\text{cdr} \ l)\) is just another way to ask for "the cdr of the list \(l\)."

What is \((\text{cdr} \ a)\) where
\[ a \) is hotdogs\]

No answer.
You cannot ask for the \(cdr\) of an atom.
What is \((\text{cdr} \ l)\) where \(l\) is ()

No answer.\(^1\)

You cannot ask for the \text{cdr} of the null list.

\(^1\) \(L: \text{nil}\)

---

## The Law of Cdr

The primitive \text{cdr} is defined only for non-empty lists. The \text{cdr} of any non-empty list is always another list.

---

What is \((\text{car} \ (\text{cdr} \ l))\) where

\[ l = ((b) \ (x \ y) \ ((c))) \]

\(x \ y)\), because \(((x \ y) \ ((c)))\) is \((\text{cdr} \ l)\), and \((x \ y)\) is the \text{car} of \((\text{cdr} \ l)\).

---

What is \((\text{cdr} \ (\text{cdr} \ l))\) where

\[ l = ((b) \ (x \ y) \ ((c))) \]

\(((c))\), because \(((x \ y) \ ((c)))\) is \((\text{cdr} \ l)\), and \(((c))\) is the \text{cdr} of \((\text{cdr} \ l)\).

---

What is \((\text{cdr} \ (\text{car} \ l))\) where

\[ l = (a \ (b \ (c)) \ d) \]

No answer, since \((\text{car} \ l)\) is an atom, and \text{cdr} does not take an atom as an argument; see The Law of Cdr.

---

What does \text{car} take as an argument?

It takes any non-empty list.

---

What does \text{cdr} take as an argument?

It takes any non-empty list.

---

What is the \text{cons} of the atom \(a\) and the list \(l\) where \(a\) is \text{peanut} and

\[ l = (\text{butter and jelly}) \]

\(\text{peanut butter and jelly})\), because \text{cons} adds an atom to the front of a list.

This can also be written "\((\text{cons} \ a \ l)\)".

Read: "\text{cons} the atom \(a\) onto the list \(l\)."

---

Toys
What is the *cons* of *s* and *l* where *s* is (banana and) and *l* is (peanut butter and jelly) ((banana and) peanut butter and jelly), because *cons* adds any S-expression to the front of a list.

What is (*cons* *s* *l*) where *s* is ((help) this) and *l* is (is very ((hard) to learn)) (((help) this) is very ((hard) to learn)).

What does *cons* take as its arguments? *cons* takes two arguments: the first one is any S-expression; the second one is any list.

What is (*cons* *s* *l*) where *s* is (a b (c)) and *l* is () ((a b (c))), because () is a list.

What is (*cons* *s* *l*) where *s* is a and *l* is () (a).

What is (*cons* *s* *l*) where *s* is ((a b c)) and *l* is *b* No answer,\(^1\) since the second argument *l* must be a list.

\(^1\) In practice, (cons α β) works for all values α and β, and
\[
\text{car } (\text{cons } \alpha \beta) = \alpha \\
\text{cdr } (\text{cons } \alpha \beta) = \beta.
\]

What is (*cons* *s* *l*) where *s* is a and *l* is *b* No answer. Why?
**The Law of Cons**

The primitive \textit{cons} takes two arguments. The second argument to \textit{cons} must be a list. The result is a list.

<table>
<thead>
<tr>
<th>Question</th>
<th>Answer</th>
</tr>
</thead>
<tbody>
<tr>
<td>What is ((\textit{cons} \ s \ (\text{car} \ l))) where (s) is a and (l) is (((b) \ c \ d))</td>
<td>(a b). Why?</td>
</tr>
<tr>
<td>What is ((\textit{cons} \ s \ (\text{cdr} \ l))) where (s) is a and (l) is (((b) \ c \ d))</td>
<td>(a c d). Why?</td>
</tr>
<tr>
<td>Is it true that the list (l) is the null list where (l) is ()</td>
<td>Yes, because it is the list composed of zero S-expressions. This question can also be written: ((\text{null}? \ l)).</td>
</tr>
<tr>
<td>What is ((\text{null}? \ (\text{quote} \ ())))</td>
<td>True, because ((\text{quote} \ ())) is a notation for the null list.</td>
</tr>
</tbody>
</table>

\(^1\) L: null

\(^1\) L: Also \(\text{'}()\). S: Also \(\text{'}\).
Is \((\text{null? } a)\) true or false where
\(a\) is spaghetti

No answer, \(^1\) because you cannot ask \text{null?} for an atom.

\(^1\) In practice, \((\text{null? } a)\) is false for everything, except the empty list.

---

**The Law of Null?**

The primitive \text{null?} is defined only for lists.

---

Is it true or false that \(s\) is an atom where \(s\) is Harry

True, because \(Harry\) is a string of characters beginning with a letter.

---

Is \((\text{atom? } s)\) true or false where
\(s\) is Harry

True, because \((\text{atom? } s)\) is just another way to ask "Is \(s\) is an atom?"

---

\[^{1}\text{ L: (defun atom? (x)\n (not (listp x)))\n S: (define atom?\n (lambda (x)\n (and (not (pair? x)) (not (null? x))))))\n}\]

---

Is \((\text{atom? } s)\) true or false where
\(s\) is \((Harry \text{ had a heap of apples})\)

False, since \(s\) is a list.

---

How many arguments does \text{atom?} take and what are they?

It takes one argument. The argument can be any S-expression.
Is \((atom? (car \ l))\) true or false where
\[\ l\ \text{is}\ \text{(Harry had a heap of apples)}\] True, because \((car \ l)\) is Harry, and Harry is an atom.

Is \((atom? (cdr \ l))\) true or false where
\[\ l\ \text{is}\ \text{(Harry had a heap of apples)}\] False.

Is \((atom? (cdr \ l))\) true or false where
\[\ l\ \text{is}\ \text{(Harry)}\] False, because the list () is not an atom.

Is \((atom? (car (cdr \ l)))\) true or false where
\[\ l\ \text{is}\ \text{(swing low sweet cherry oat)}\] True, because \((cdr \ l)\) is (low sweet cherry oat), and \((car (cdr \ l))\) is low, which is an atom.

Is \((atom? (car (cdr \ l)))\) true or false where
\[\ l\ \text{is}\ \text{(swing (low sweet) cherry oat)}\] False, since \((cdr \ l)\) is ((low sweet) cherry oat), and \((car (cdr \ l))\) is (low sweet), which is a list.

True or false: \(a1\) and \(a2\) are the same atom where \(a1\) is Harry and \(a2\) is Harry
True, because \(a1\) is the atom Harry and \(a2\) is the atom Harry.

Is \((eq? \ a1 \ a2)\) true or false where \(a1\) is Harry and \(a2\) is Harry
True, because \((eq? \ a1 \ a2)\) is just another way to ask, “Are \(a1\) and \(a2\) the same non-numeric atom?”

\[1\ \text{L: eq}\]

Is \((eq? \ a1 \ a2)\) true or false where \(a1\) is margarine and \(a2\) is butter
False, since \(a1\) and \(a2\) are different atoms.
How many arguments does \textit{eq}? take and what are they? 

It takes two arguments. Both of them must be non-numeric atoms.

Is \((eq? \ l1 \ l2)\) true or false where \(l1\) is () and \(l2\) is (strawberry) 

No answer,\(^1\) () and (strawberry) are lists.

\(^1\) In practice, lists may be arguments of \textit{eq}?. Two lists are \textit{eq}? if they are the same list.

Is \((eq? \ n1 \ n2)\) true or false where \(n1\) is 6 and \(n2\) is 7 

No answer,\(^1\) 6 and 7 are numbers.

\(^1\) In practice, some numbers may be arguments of \textit{eq}?.

\begin{center}
\textbf{The Law of Eq?}
\end{center}

The primitive \textit{eq}? takes two arguments. Each must be a non-numeric atom.

Is \((eq? \ (\textit{car} \ l) \ a)\) true or false where \(l\) is (Mary had a little lamb chop) and \(a\) is Mary 

True, because \((\textit{car} \ l)\) is the atom Mary, and the argument \(a\) is also the atom Mary.

Is \((eq? \ (\textit{cdr} \ l) \ a)\) true or false where \(l\) is (soured milk) and \(a\) is milk 

No answer. See The Laws of Eq? and Cdr.
Is \((eq\ (car\ l)\ (car\ (cdr\ l)))\) true or false where
\(l\) is (beans beans we need jelly beans)

True, because it compares the first and second atoms in the list.

⇒ Now go make yourself a peanut butter and jelly sandwich. ⇐

Write the function \(\text{lat?}\) using some, but not necessarily all, of the following functions: \(\text{car} \; \text{cdr} \; \text{cons} \; \text{null?} \; \text{atom?} \; \text{and} \; \text{eq?}\) 

You were not expected to be able to do this yet, because you are still missing some ingredients. Go on to the next question. Good luck.

---

Are you rested?
\[(\text{define } \text{lat?} l)\]
\[(\lambda (l) \text{ cond})\]
\[
(\text{null? } l) \#t
\]
\[(\text{atom? } (\text{car } l)) \text{ (lat? } (\text{cdr } l))\]
\[(\text{else } \#f))\]  

What is the value of \((\text{lat? } l)\) 
where 
\(l\) is the argument \((\text{bacon and eggs})\)

---

\[1\] L: \(\text{defun lat? } (l)\)
\[\text{(cond})\]
\[
(\text{null } l) \text{ t}
\]
\[(\text{atom? } (\text{car } l)) \text{ (lat? } (\text{cdr } l))\]
\[(\text{t nil}))\]

---

How do we determine the answer \#t for the application \((\text{lat? } l)\) 
You were not expected to know this one either. The answer is determined by answering the questions asked by \(\text{lat?}\)  
Hint: Write down the definition of the function \(\text{lat?}\) and refer to it for the next group of questions.

---

What is the first question asked by \((\text{lat? } l)\) \((\text{null? } l)\) 
Note: 
\((\text{cond} \ldots)\) asks questions; 
\((\text{lambda} \ldots)\) creates a function; and 
\((\text{define} \ldots)\) gives it a name.

---

What is the meaning of the \textbf{cond}-line \((\text{null? } l) \#t)\) 
where 
\(l\) is \((\text{bacon and eggs})\) 
\((\text{null? } l)\) asks if the argument \(l\) is the null list. If it is, the value of the application is true. If it is not, we ask the next question. In this case, \(l\) is not the null list, so we ask the next question.

---

What is the next question? \((\text{atom? } (\text{car } l)).\)
What is the meaning of the line
\[ ((\text{atom? } (\text{car } l)) \ (\text{lat? } (\text{cdr } l))) \]
where
\[ l \text{ is (bacon and eggs)} \]
\((\text{atom? } (\text{car } l))\) asks if the first S-expression of the list \(l\) is an atom. If \((\text{car } l)\) is an atom, we want to know if the rest of \(l\) is also composed only of atoms. If \((\text{car } l)\) is not an atom, we ask the next question. In this case, \((\text{car } l)\) is an atom, so the value of the function is the value of \((\text{lat? } (\text{cdr } l))\).

What is the meaning of \((\text{lat? } (\text{cdr } l))\)

\((\text{lat? } (\text{cdr } l))\) finds out if the rest of the list \(l\) is composed only of atoms, by referring to the function with a new argument.

Now what is the argument \(l\) for \(\text{lat?}\)

Now the argument \(l\) is \((\text{cdr } l)\), which is \((\text{and eggs})\).

What is the next question?

\((\text{null? } l)\).

What is the meaning of the line
\[ ((\text{null? } l) \ #t ) \]
where
\[ l \text{ is now (and eggs)} \]
\((\text{null? } l)\) asks if the argument \(l\) is the null list. If it is, the value of the application is \(#t\). If it is not, we ask the next question. In this case, \(l\) is not the null list, so we ask the next question.

What is the next question?

\((\text{atom? } (\text{car } l))\).

What is the meaning of the line
\[ ((\text{atom? } (\text{car } l)) \ (\text{lat? } (\text{cdr } l))) \]
where
\[ l \text{ is (and eggs)} \]
\((\text{atom? } (\text{car } l))\) asks if \((\text{car } l)\) is an atom. If it is an atom, the value of the application is \((\text{lat? } (\text{cdr } l))\). If not, we ask the next question. In this case, \((\text{car } l)\) is an atom, so we want to find out if the rest of the list \(l\) is composed only of atoms.

What is the meaning of \((\text{lat? } (\text{cdr } l))\)

\((\text{lat? } (\text{cdr } l))\) finds out if the rest of \(l\) is composed only of atoms, by referring again to the function \(\text{lat?}\), but this time, with the argument \((\text{cdr } l)\), which is \((\text{eggs})\).

*Do It, Do It Again, and Again, and Again ...*
What is the next question?

What is the meaning of the line

\((null? l) \ #t\)

where

\(l\) is now \((\text{eggs})\)

\((null? l)\) asks if the argument \(l\) is the null list. If it is, the value of the application is \(#t\) — true. If it is not, move to the next question. In this case, \(l\) is not null, so we ask the next question.

What is the next question?

What is the meaning of the line

\((atom? (\text{car } l)) (lat? (\text{cdr } l))\)

where

\(l\) is now \((\text{eggs})\)

\((atom? (\text{car } l))\) asks if \((\text{car } l)\) is an atom. If it is, the value of the application is \((lat? (\text{cdr } l))\). If \((\text{car } l)\) is not an atom, ask the next question. In this case, \((\text{car } l)\) is an atom, so once again we look at \((lat? (\text{cdr } l))\).

What is the meaning of \((lat? (\text{cdr } l))\)

\((lat? (\text{cdr } l))\) finds out if the rest of the list \(l\) is composed only of atoms, by referring to the function \(lat?\), with \(l\) becoming the value of \((\text{cdr } l)\).

Now, what is the argument for \(lat?\)

\((\text{})\).

What is the meaning of the line

\((null? l) \ #t\)

where

\(l\) is now \((\text{})\)

\((null? l)\) asks if the argument \(l\) is the null list. If it is, the value of the application is the value of \(#t\). If not, we ask the next question. In this case, \((\text{})\) is the null list. So, the value of the application \((lat? l)\) where

\(l\) is \((\text{bacon and eggs})\), is \(#t\) — true.

Do you remember the question about \((lat? l)\)

Probably not. The application \((lat? l)\) has the value \(#t\) if the list \(l\) is a list of atoms where

\(l\) is \((\text{bacon and eggs})\).
Can you describe what the function \textit{lat} does in your own words?

Here are our words:

"\textit{lat} looks at each S-expression in a list, in turn, and asks if each S-expression is an atom, until it runs out of S-expressions. If it runs out without encountering a list, the value is \#t. If it finds a list, the value is \#f—false."

To see how we could arrive at a value of "false," consider the next few questions.

This is the function \textit{lat} again:

\begin{verbatim}
(define lat?
  (lambda (l)
    (cond
      ((null? l) #t)
      ((atom? (car l)) (lat? (cdr l)))
      (else #f))))
\end{verbatim}

What is the value of \textit{(lat? l)} where \textit{l} is now \textit{(bacon (and eggs))}?

Do It, Do It Again, and Again, and Again ...

Here are our words:

"\textit{lat} looks at each S-expression in a list, in turn, and asks if each S-expression is an atom, until it runs out of S-expressions. If it runs out without encountering a list, the value is \#t. If it finds a list, the value is \#f—false."

To see how we could arrive at a value of "false," consider the next few questions.

This is the function \textit{lat} again:

\begin{verbatim}
(define lat?
  (lambda (l)
    (cond
      ((null? l) #t)
      ((atom? (car l)) (lat? (cdr l)))
      (else #f))))
\end{verbatim}

What is the value of \textit{(lat? l)} where \textit{l} is now \textit{(bacon (and eggs))}?

\begin{itemize}
  \item \textit{(null? l)}.
  \item \textit{(null? l)} asks if \textit{l} is the null list. If it is, the value is \#t. If \textit{l} is not null, move to the next question. In this case, it is not null, so we ask the next question.
  \item \textit{(atom? (car l))}.
  \item \textit{(atom? (car l))} asks if \textit{(car l)} is an atom. If it is, the value is \textit{(lat? (cdr l))}. If it is not, we ask the next question. In this case, \textit{(car l)} is an atom, so we want to check if the rest of the list \textit{l} is composed only of atoms.
\end{itemize}
What is the meaning of \((\text{lat?} \ (\text{cdr} \ l))\)?

\((\text{lat?} \ (\text{cdr} \ l))\) checks to see if the rest of the list \(l\) is composed only of atoms, by referring to \(\text{lat?}\) with \(l\) replaced by \((\text{cdr} \ l)\).

What is the meaning of the line \((\text{null?} \ l) \ #t\) where \(l\) is now \(((\text{and eggs}))\)?

\((\text{null?} \ l)\) asks if \(l\) is the null list. If it is null, the value is \(#t\). If it is not null, we ask the next question. In this case, \(l\) is not null, so move to the next question.

What is the next question?

\((\text{atom?} \ (\text{car} \ l)).\)

What is the meaning of the line \(((\text{atom?} \ (\text{car} \ l)) \ (\text{lat?} \ (\text{cdr} \ l)))\) where \(l\) is now \(((\text{and eggs}))\)?

\((\text{atom?} \ (\text{car} \ l))\) asks if \((\text{car} \ l)\) is an atom. If it is, the value is \((\text{lat?} \ (\text{cdr} \ l))\). If it is not, we move to the next question. In this case, \((\text{car} \ l)\) is not an atom, so we ask the next question.

What is the next question? else.

What is the meaning of the question else?

else asks if else is true.

Is else true?

Yes, because the question else is always true!

else

Of course.

Why is else the last question?

Because we do not need to ask any more questions.

Why do we not need to ask any more questions?

Because a list can be empty, can have an atom in the first position, or can have a list in the first position.

What is the meaning of the line else \#f

else asks if else is true. If else is true—as it always is—then the answer is \#f—false.
What is \((lat? l)\)

Can you describe how we determined the value \(#f\) for \((lat? l)\) where \(l\) is \((\text{bacon (and eggs)})\)?

Here is one way to say it:

"\((lat? l)\) looks at each item in its argument to see if it is an atom. If it runs out of items before it finds a list, the value of \((lat? l)\) is \(#t\). If it finds a list, as it did in the example \((\text{bacon (and eggs)})\), the value of \((lat? l)\) is \(#f\)."

Is \((\text{or (null? l1) (atom? l2)})\) true or false where \(l1\) is ()

and \(l2\) is \((d e f g)\)

True, because \((\text{null? l1})\) is true where \(l1\) is ().

Is \((\text{or (null? l1) (null? l2)})\) true or false where \(l1\) is \((a b c)\)

and \(l2\) is ()

True, because \((\text{null? l2})\) is true where \(l2\) is ().

Is \((\text{or (null? l1) (null? l2)})\) true or false where \(l1\) is \((a b c)\)

and \(l2\) is \((\text{atom})\)

False, because neither \((\text{null? l1})\) nor \((\text{null? l2})\) is true where \(l1\) is \((a b c)\)

and \(l2\) is \((\text{atom})\).

What does \((\text{or ...})\) do?

\((\text{or ...})\) asks two questions, one at a time. If the first one is true it stops and answers true. Otherwise it asks the second question and answers with whatever the second question answers.
Is it true or false that \( a \) is a member of \( \text{lat} \) where \( a \) is tea and 
\[ \text{lat} \text{ is (coffee tea or milk)} \]

True, because one of the atoms of the lat, (coffee tea or milk) is the same as the atom \( a \)--tea.

Is \((\text{member? } a \text{ lat})\) true or false where \( a \) is poached and 
\[ \text{lat} \text{ is (fried eggs and scrambled eggs)} \]

False, since \( a \) is not one of the atoms of the lat.

This is the function \( \text{member?} \):

\[
\text{(define } \text{member?} \\
\text{ (lambda } (a \text{ lat}) \\
\text{ (cond \\
\text{ ((null? lat) #f) \\
\text{ (else (or (eq? (car lat) a) \\
\text{ (member? a (cdr lat))))))}) \\
\text{))})}
\]

What is the value of \((\text{member? } a \text{ lat})\) where \( a \) is meat and 
\[ \text{lat} \text{ is (mashed potatoes and meat gravy)} \]

\( \#t \), because the atom meat is one of the atoms of \( \text{lat} \), (mashed potatoes and meat gravy).

How do we determine the value \( \#t \) for the above application?

The value is determined by asking the questions about \((\text{member? } a \text{ lat})\).

Hint: Write down the definition of the function \( \text{member?} \) and refer to it while you work on the next group of questions.

What is the first question asked by \((\text{member? } a \text{ lat})\) 

\( (\text{null? lat}). \)

This is also the first question asked by \( \text{lat?} \).
The First Commandment

*(preliminary)*

Always ask *null?* as the first question in expressing any function.

What is the meaning of the line

```
((null? lat) #f)
```

where

*lat* is (mashed potatoes and meat gravy)

*(null? lat)* asks if *lat* is the null list. If it is, the value is #f, since the atom meat was not found in *lat*. If not, we ask the next question. In this case, it is not null, so we ask the next question.

What is the next question?

*else.*

Why is *else* the next question?

Because we do not need to ask any more questions.

Is *else* really a question?

Yes, *else* is a question whose value is always true.

What is the meaning of the line

```
(else (or (eq? (car lat) a)
(member? a (cdr lat))))
```

Now that we know that *lat* is not *null?*, we have to find out whether the *car* of *lat* is the same atom as *a*, or whether *a* is somewhere in the rest of *lat*. The answer

```
(or (eq? (car lat) a)
(member? a (cdr lat)))
```

does this.

True or false:

```
(or (eq? (car lat) a)
(member? a (cdr lat)))
```

where *a* is meat and

*lat* is (mashed potatoes and meat gravy)

We will find out by looking at each question in turn.

<tr>
<td>What do we do now?</td>
<td>Since ((\text{null}? \ \text{lat})) is false, ask the next question.</td>
</tr>
<tr>
<td>What is the next question?</td>
<td>\textit{else}.</td>
</tr>
</tbody>
</table>

\textit{Do It, Do It Again, and Again, and Again . . .}
What is the value of
(or (eq? (car lat) a)
  (member? a (cdr lat)))
	#t, because (car lat), which is meat, and a, which is meat, are the same atom. Therefore, (or ...) answers with #t.

What is the value of the application
(member? a lat)
where a is meat
and
lat is (meat gravy)
	#t, because we have found that meat is a member of (meat gravy).

What is the value of the application
(member? a lat)
where a is meat
and
lat is (and meat gravy)
	#t, because meat is also a member of the lat (and meat gravy).

What is the value of the application
(member? a lat)
where a is meat
and
lat is (potatoes and meat gravy)
	#t, because meat is also a member of the lat (potatoes and meat gravy).

What is the value of the application
(member? a lat)
where a is meat
and
lat is (mashed potatoes and meat gravy)
	#t, because meat is also a member of the lat (mashed potatoes and meat gravy).

Of course, this is our original lat.

Just to make sure you have it right, let's quickly run through it again. What is the value of (member? a lat)
where
a is meat
and
lat is (mashed potatoes and meat gravy)
	#t.

Hint: Write down the definition of the function member? and its arguments and refer to them as you go through the next group of questions.

Null? lat

No. Move to the next line.

\]

\[
\text{Yes, the value is } \#t .
\]
What is the value of \((\text{member? } a \text{ lat})\) where \(a\) is meat and \(lat\) is (meat gravy)? #t.

What is the value of \((\text{member? } a \text{ lat})\) where \(a\) is meat and \(lat\) is (and meat gravy)? #t.

What is the value of \((\text{member? } a \text{ lat})\) where \(a\) is meat and \(lat\) is (potatoes and meat gravy)? #t.

What is the value of \((\text{member? } a \text{ lat})\) where \(a\) is meat and \(lat\) is (mashed potatoes and meat gravy)? #t.

What is the value of \((\text{member? } a \text{ lat})\) where \(a\) is liver and \(lat\) is (bagels and lox)? #f.

Let's work out why it is #f. What's the first question \(\text{member?}\) asks? (null? lat).

(null? lat) No. Move to the next line.
else

Yes, but \((eq\?\ (car\ lat)\ a)\) is false.
Recur with \(a\) and \((cdr\ lat)\) where \(a\) is liver
and
\((cdr\ lat)\) is \((and\ lox)\).

\((null?\ lat)\)

No. Move to the next line.

else

Yes, but \((eq\?\ (car\ lat)\ a)\) is false.
Recur with \(a\) and \((cdr\ lat)\) where \(a\) is liver
and
\((cdr\ lat)\) is \((lox)\).

\((null?\ lat)\)

No. Move to the next line.

else

Yes, but \((eq\?\ (car\ lat)\ a)\) is still false.
Recur with \(a\) and \((cdr\ lat)\)
where \(a\) is liver
and
\((cdr\ lat)\) is \((\)\).

\((null?\ lat)\)

Yes.

What is the value of \((member?\ a\ lat)\) where \(a\) is liver
and
\(lat\) is \((\)\)

#f.

What is the value of
\(\textbf{(or}\ (eq\?\ (car\ lat)\ a)\)
\((member?\ a\ (cdr\ lat)))\)
where
\(a\) is liver
and
\(lat\) is \((lox)\)

#f.
What is the value of \((\text{member? } a \text{ lat})\) where \(a\) is liver and \(\text{lat}\) is \((\text{lox})\)

What is the value of
\[
(\text{or} \ (\text{eq?} \ (\text{car} \ \text{lat}) \ a) \\
(\text{member?} \ a \ (\text{cdr} \ \text{lat})))
\]
where
\(a\) is liver and
\(\text{lat}\) is \((\text{and} \ \text{lox})\)

What is the value of \((\text{member? } a \text{ lat})\) where \(a\) is liver and \(\text{lat}\) is \((\text{and} \ \text{lox})\)

What is the value of
\[
(\text{or} \ (\text{eq?} \ (\text{car} \ \text{lat}) \ a) \\
(\text{member?} \ a \ (\text{cdr} \ \text{lat})))
\]
where
\(a\) is liver and
\(\text{lat}\) is \((\text{bagels and} \ \text{lox})\)

What is the value of \((\text{member? } a \text{ lat})\) where \(a\) is liver and \(\text{lat}\) is \((\text{bagels and} \ \text{lox})\)
Do you believe all this? Then you may rest!

This space for doodling
3.

Cons the Magnificent
| \textbf{What is} \((\text{rember a lat})\) \where \(a\) \text{ is mint} \and \(\text{lat}\) \text{ is (lamb chops and mint jelly)} | \text{What does} \((\text{rember a lat})\) \text{ do?} | \text{It takes an atom and a lat as its arguments,} \\
| \begin{align*} 
&(\text{rember a lat}) \\
&\where \(a\) \text{ is mint} \\
&\and \(\text{lat}\) \text{ is (lamb chops and mint jelly)} \\
&\text{do?} \\
\end{align*} | \begin{align*} 
&\text{First we will test} \(\text{null? lat}\) - \text{The First} \\
&\text{Commandment.} \\
\end{align*} |

| \text{What steps should we use to do this?} | \text{Return} \(()\). |

| \text{And if} \((\text{null? lat})\) \text{ is true?} | \text{We know that there must be at least one} \\
| \text{What do we know if} \((\text{null? lat})\) \text{ is not true?} | \text{atom in the lat.} |

| \text{Is there any other question we should ask} \text{ about the lat?} | \text{No. Either a lat is empty or it contains at} \\
| \text{Cons the Magnificent} | \text{least one atom.} |
What do we do if we know that the lat contains at least one atom? We ask whether \( a \) is equal to \((\text{car \ lat})\).

How do we ask questions? By using:
\[
\text{(cond}
\begin{array}{c}
(\quad \quad \quad ) \\
(\quad \quad \quad)
\end{array}
\text{)}
\]

How do we ask if \( a \) is the same as \((\text{car \ lat})\)? \((eq? (\text{car \ lat}) \ a)\).

What would be the value of \((\text{rember \ a \ lat})\) if \( a \) were the same as \((\text{car \ lat})\)? \((\text{cdr \ lat})\).

What do we do if \( a \) is not the same as \((\text{car \ lat})\)? We want to keep \((\text{car \ lat})\), but also find out if \( a \) is somewhere in the rest of the lat.

How do we remove the first occurrence of \( a \) in the rest of \( \text{lat} \)? \((\text{rember \ a \ (cdr \ lat)})\).

Is there any other question we should ask? No.

Now, let's write down what we have so far:

\[
\text{(define \ \text{rember}}
\begin{array}{c}
\text{(lambda \ (a \ lat))} \\
\text{(cond}
\begin{array}{c}
((\text{null? \ lat}) \ (\text{quote \ ())}) \\
\text{(else \ (cond}
\begin{array}{c}
((eq? \ (\text{car \ lat}) \ a) \ (\text{cdr \ lat})) \\
\text{(else \ \ (rember \ a}
\begin{array}{c}
\text{(cdr \ lat)))\))))))
\end{array}
\end{array}
\end{array}
\end{array}
\)\]

What is the value of \((\text{rember \ a \ lat})\) where \( a \) is \( \text{bacon} \) and \( \text{lat} \) is \((\text{bacon \ lettuce \ and \ tomato})\)?

Hint: Write down the function \text{rember} and its arguments, and refer to them as you go through the next sequence of questions.
Now, let's see if this function works. What is the first question?

<table>
<thead>
<tr>
<th>What do we do now?</th>
<th>Move to the next line and ask the next question.</th>
</tr>
</thead>
<tbody>
<tr>
<td>else</td>
<td>Yes.</td>
</tr>
<tr>
<td>What next?</td>
<td>Ask the next question.</td>
</tr>
</tbody>
</table>

(eq? (car lat) a)

| Yes, so the value is (cdr lat). In this case, it is the list (lettuce and tomato). |

Is this the correct value?

| Yes, because it is the original list without the atom bacon. |

But did we really use a good example?

| Who knows? But the proof of the pudding is in the eating, so let's try another example. |

What does **rember** do?

| It takes an atom and a lat as its arguments, and makes a new lat with the first occurrence of the atom in the old lat removed. |

What do we do now?

| We compare each atom of the lat with the atom a, and if the comparison fails we build a list that begins with the atom we just compared. |

What is the value of (**rember a lat**) where a is and and lat is (bacon lettuce and tomato)

(bacon lettuce tomato).

**Cons the Magnificent**
Let us see if our function `rember` works. What is the first question asked by `rember`?

What do we do now? Move to the next line, and ask the next question.

`else` Okay, so ask the next question.

`(eq? (car lat) a)` No, so move to the next line.

What is the meaning of `(else (rember a (cdr lat)))`?

`else` asks if `else` is true—as it always is—and the rest of the line says to recur with `a` and `(cdr lat)`, where `a` is and `(cdr lat)` is `(lettuce and tomato)`.

`(null? lat)` No, so move to the next line.

`else` Sure.

`(eq? (car lat) a)` No, so move to the next line.

What is the meaning of `(rember a (cdr lat))`? Recur where `a` is and `(cdr lat)` is `(and tomato)`.

`(null? lat)` No, so move to the next line, and ask the next question.

`else` Of course.
(eq? (car lat) a)  
Yes.

So what is the result?  
(cdr lat)—(tomato).

Is this correct?  
No, since (tomato) is not the list 
(bacon lettuce and tomato) 
with just a—and—removed.

What did we do wrong?  
We dropped and, but we also lost all the 
atoms preceding and.

How can we keep from losing the atoms 
bacon and lettuce 
We use Cons the Magnificent. Remember 
cons, from chapter 1?

The Second Commandment
Use cons to build lists.

Let’s see what happens when we use cons  
(bacon lettuce tomato).

Hint: Make a copy of this function with 
cons and the arguments a and lat so you 
can refer to it for the following questions.

(define rember  
(lambda (a lat)  
(cond  
  ((null? lat) (quote ()))  
  (else (cond  
           ((eq? (car lat) a) (cdr lat))  
           (else (cons (car lat)  
                        (rember a  
                         (cdr lat))))))))))

What is the value of (rember a lat)  
where a is and 
and 
lat is (bacon lettuce and tomato)
<table>
<thead>
<tr>
<th>What is the first question?</th>
<th>(null? lat).</th>
</tr>
</thead>
<tbody>
<tr>
<td>What do we do now?</td>
<td>Ask the next question.</td>
</tr>
<tr>
<td><strong>else</strong></td>
<td>Yes, of course.</td>
</tr>
<tr>
<td><strong>(eq? (car lat) a)</strong></td>
<td>No, so move to the next line.</td>
</tr>
</tbody>
</table>

| What is the meaning of      | It says to *cons* the *car* of *lat*—bacon—onto the value of (*rember a (cdr lat)*). But since we don’t know the value of (*rember a (cdr lat)*), we must find it before we can *cons (car lat)* onto it. |
| (**cons (car lat)**         | This refers to the function with *lat* replaced by (*cdr lat*)—(lettuce and tomato). |
| (**rember a**               | No, so move to the next line. |
| (**cdr lat)**               | Yes, ask the next question. |
| (**(eq? (car lat) a)**      | No, so move to the next line. |

<p>| What is the meaning of      | It says to <em>cons</em> the <em>car</em> of <em>lat</em>—lettuce—onto the value of (<em>rember a (cdr lat)</em>). But since we don’t know the value of (<em>rember a (cdr lat)</em>), we must find it before we can <em>cons (car lat)</em> onto it. |
| (<strong>cons (car lat)</strong>         |  |
| (<strong>rember a</strong>               |  |
| (<strong>cdr lat)</strong>               |  |</p>
<table>
<thead>
<tr>
<th>What is the meaning of ((\text{remember } a \ (\text{cdr } \text{lat})))</th>
<th>This refers to the function with (\text{lat}) replaced by ((\text{cdr } \text{lat})), that is, ((\text{and } \text{tomato})).</th>
</tr>
</thead>
<tbody>
<tr>
<td>((\text{null? } \text{lat}))</td>
<td>No, so ask the next question.</td>
</tr>
<tr>
<td>else</td>
<td>Still.</td>
</tr>
<tr>
<td>((\text{eq? } (\text{car } \text{lat}) \ a))</td>
<td>Yes.</td>
</tr>
<tr>
<td>What is the value of the line (((\text{eq? } (\text{car } \text{lat}) \ a) \ (\text{cdr } \text{lat})))</td>
<td>((\text{cdr } \text{lat})-(\text{tomato})).</td>
</tr>
<tr>
<td>Are we finished?</td>
<td>Certainly not! We know what ((\text{remember } a \ \text{lat})) is when (\text{lat}) is ((\text{and } \text{tomato})), but we don’t yet know what it is when (\text{lat}) is ((\text{lettuce and tomato})) or ((\text{bacon lettuce and tomato})).</td>
</tr>
<tr>
<td>We now have a value for ((\text{remember } a \ (\text{cdr } \text{lat}))) where (a) is and and ((\text{cdr } \text{lat})) is ((\text{and } \text{tomato}))</td>
<td>Recall that we wanted to \text{cons} lettuce onto the value of ((\text{remember } a \ (\text{cdr } \text{lat}))) where (a) was and and ((\text{cdr } \text{lat})) was ((\text{and } \text{tomato})). Now that we have this value, which is ((\text{tomato})), we can \text{cons} lettuce onto it.</td>
</tr>
<tr>
<td>This value is ((\text{tomato}))</td>
<td></td>
</tr>
<tr>
<td>What next?</td>
<td></td>
</tr>
<tr>
<td>What is the result when we \text{cons} lettuce onto ((\text{tomato}))</td>
<td>((\text{lettuce tomato})).</td>
</tr>
<tr>
<td>What does ((\text{lettuce tomato})) represent?</td>
<td>It represents the value of ((\text{cons } (\text{car } \text{lat})) (\ (\text{remember } a) (\ (\text{cdr } \text{lat})))), when (\text{lat}) is ((\text{lettuce and tomato})) and ((\text{remember } a \ (\text{cdr } \text{lat}))) is ((\text{tomato})).</td>
</tr>
</tbody>
</table>
Are we finished yet?  

Not quite. So far we know what \((\text{记住 a lat})\) is when \(\text{lat}\) is (lettuce and tomato), but we don’t yet know what it is when \(\text{lat}\) is (bacon lettuce and tomato).

We now have a value for \((\text{记住 a (cdr lat)})\)
where a is and 
and  
\((\text{cdr lat})\) is (lettuce and tomato) 
This value is (lettuce tomato) 
This is not the final value, so what must we do again? 

Recall that, at one time, we wanted to \text{cons} bacon onto the value of \((\text{记住 a (cdr lat)})\), where  
\(a\) was and 
and  
\((\text{cdr lat})\) was (lettuce and tomato). 
Now that we have this value, which is (lettuce tomato), we can \text{cons} bacon onto it.

What is the result when we \text{cons} bacon onto  
(lettuce tomato) 

(bacon lettuce tomato).

What does (bacon lettuce tomato) represent?\(^\dagger\) 

It represents the value of  
\((\text{cons (car lat)})\)  
\((\text{记住 a (cdr lat)})\), 
when  
\(\text{lat}\) is (bacon lettuce and tomato) 
and  
\((\text{记住 a (cdr lat)})\) is (lettuce tomato).

\(^\dagger\) Lunch?

Are we finished yet? 

Yes.

Can you put in your own words how we determined the final value  
(bacon lettuce tomato) 

In our words:  
“The function \text{记住} checked each atom of the \text{lat}, one at a time, to see if it was the same as the atom and. If the \text{car} was not the same as the atom, we saved it to be \text{consed} to the final value later. When \text{记住} found the atom and, it dropped it, and \text{consed} the previous atoms back onto the rest of the \text{lat}.”
Can you rewrite `rember` so that it reflects the above description?

Yes, we can simplify it.

```scheme
(define rember
  (lambda (a lat)
    (cond
      ((null? lat) (quote ()))
      ((eq? (car lat) a) (cdr lat))
      (else (cons (car lat)
                   (rember a (cdr lat)))))))
```

Do you think this is simpler?

Functions like `rember` can always be simplified in this manner.

So why don’t we simplify right away?

Because then a function’s structure does not coincide with its argument’s structure.

Let’s see if the new `rember` is the same as the old one. What is the value of the application `(rember a lat)` where `a` is and `lat` is `(bacon lettuce tomato)`

(bacon lettuce tomato).

Hint: Write down the function `rember` and its arguments and refer to them as you go through the next sequence of questions.

<table>
<thead>
<tr>
<th>Case</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>(null? lat)</code></td>
<td>No</td>
</tr>
<tr>
<td><code>(eq? (car lat) a)</code></td>
<td>No</td>
</tr>
</tbody>
</table>
| `else`       | Yes, so the value is `(cons (car lat)
                               (rember a (cdr lat)))`. |

What is the meaning of `(cons (car lat)
                          (rember a (cdr lat)))`?

This says to refer to the function `rember` but with the argument `lat` replaced by `(cdr lat)`, and that after we arrive at a value for `(rember a (cdr lat))` we must `cons
` (car lat)—bacon—onto it.
(null? lat)  No.

(eq? (car lat) a)  No.

else

Yes, so the value is
   (cons (car lat)
   (rember a (cdr lat))).

What is the meaning of
   (cons (car lat)
   (rember a (cdr lat)))
This says we recur using the function rember, with the argument lat replaced by (cdr lat), and that after we arrive at a value for (rember a (cdr lat)), we must cons (car lat)—lettuce—onto it.

(now? lat)  No.

(eq? (car lat) a)  Yes.

What is the value of the line
   ((eq? (car lat) a) (cdr lat))
It is (cdr lat)—(tomato).

Now what?
Now cons (car lat)—lettuce—onto (tomato).

Now what?
Now cons (car lat)—bacon—onto (lettuce tomato).

Now that we have completed rember try this example: (rember a lat)
where a is sauce and
   lat is (soy sauce and tomato sauce)
   (rember a lat) is (soy and tomato sauce).
<table>
<thead>
<tr>
<th>What is ((firsts\ l)) where (l) is (apple peach pumpkin) (plum pear cherry) (grape raisin pea) (bean carrot eggplant))</th>
<th>(apple plum grape bean).</th>
</tr>
</thead>
<tbody>
<tr>
<td>What is ((firsts\ l)) where (l) is ((a b) (c d) (e f))</td>
<td>(a c e).</td>
</tr>
<tr>
<td>What is ((firsts\ l)) where (l) is ()</td>
<td>()</td>
</tr>
<tr>
<td>What is ((firsts\ l)) where (l) is ((five plums) (four) (eleven green oranges))</td>
<td>(five four eleven).</td>
</tr>
<tr>
<td>What is ((firsts\ l)) where (l) is (((five plums) four) (eleven green oranges) ((no) more))</td>
<td>((five plums) eleven (no)).</td>
</tr>
</tbody>
</table>

In your own words, what does \((firsts\ l)\) do? We tried the following: “The function \(firsts\) takes one argument, a list, which is either a null list or contains only non-empty lists. It builds another list composed of the first S-expression of each internal list.”
See if you can write the function \texttt{firsts}

Remember the Commandments!

This much is easy:

\begin{verbatim}
(define firsts
  (lambda (l)
    (cond
      ((null? l) ...) 
      (else (cons ... (firsts (cdr l)))))))
\end{verbatim}

\begin{itemize}
  \item Why \(\texttt{(define firsts (lambda (l) \ldots))}\)
    \begin{itemize}
      \item Because we always state the function name, \texttt{(lambda, and the argument(s) of the function.}
    \end{itemize}
  \item Why \(\texttt{(cond \ldots)}\)
    \begin{itemize}
      \item Because we need to ask questions about the actual arguments.
    \end{itemize}
  \item Why \(\texttt{((null? l) \ldots)}\)
    \begin{itemize}
      \item The First Commandment.
    \end{itemize}
  \item Why \(\texttt{(else)}\)
    \begin{itemize}
      \item Because we only have two questions to ask about the list \(l\): either it is the null list, or it contains at least one non-empty list.
    \end{itemize}
  \item Why \(\texttt{(else)}\)
    \begin{itemize}
      \item See above. And because the last question is always \texttt{else.}
    \end{itemize}
  \item Why \(\texttt{(cons)}\)
    \begin{itemize}
      \item Because we are building a list—The Second Commandment.
    \end{itemize}
  \item Why \(\texttt{(firsts (cdr l))}\)
    \begin{itemize}
      \item Because we can only look at one S-expression at a time. To look at the rest, we must recur.
    \end{itemize}
  \item Why \(\texttt{}\)
    \begin{itemize}
      \item Because these are the matching parentheses for \texttt{(cond, (lambda, and (define, and they always appear at the end of a function definition.}
    \end{itemize}
\end{itemize}
Keeping in mind the definition of `(firsts l)` what is a typical element of the value of `(firsts l)` where

\[ l = ((a b) (c d) (e f)) \]

What is another typical element? c, or even e.

Consider the function `seconds`
What would be a typical element of the value of `(seconds l)` where

\[ l = ((a b) (c d) (e f)) \]

How do we describe a typical element for `(firsts l)`
As the `car` of an element of \( l - (\text{car} (\text{car} l)) \). See chapter 1.

When we find a typical element of `(firsts l)` what do we do with it?
`cons` it onto the recursion—`(firsts (cdr l))`.

---

**The Third Commandment**

When building a list, describe the first typical element, and then `cons` it onto the natural recursion.

With The Third Commandment, we can now fill in more of the function `firsts`
What does the last line look like now?

\[
\text{(else (cons (car (car l)) (firsts (cdr l)))).}
\]

Cons the Magnificent
What does \textit{(firsts \ l)} do

define firsts
  (lambda (l)
    (cond
      ((null? l) ...)
      (else (cons (car (car l))
               (firsts (cdr l)))))))

where \(l\) is \((\text{a b}) \ (\text{c d}) \ (\text{e f})\)

\textit{(null? \ l)} where \(l\) is \((\text{a b}) \ (\text{c d}) \ (\text{e f})\)

No, so move to the next line.

What is the meaning of
  \((\text{cons (car (car l)) (firsts (cdr l))})\)

It saves \((\text{car (car l)})\) to \textit{cons} onto \((\text{firsts (cdr l)})\). To find \((\text{firsts (cdr l)})\), we refer to the function with the new argument \((\text{cdr l})\).

\textit{(null? \ l)} where \(l\) is \((\text{c d}) \ (\text{e f})\)

No, so move to the next line.

What is the meaning of
  \((\text{cons (car (car l)) (firsts (cdr l))})\)

Save \((\text{car (car l)})\), and recur with \((\text{firsts (cdr l)})\).

\textit{(null? \ l)} where \(l\) is \((\text{e f})\)

No, so move to the next line.

What is the meaning of
  \((\text{cons (car (car l)) (firsts (cdr l))})\)

Save \((\text{car (car l)})\), and recur with \((\text{firsts (cdr l)})\).

\textit{(null? \ l)}

Yes.

Now, what is the value of the line
  \textit{((null? \ l) ...)}

There is no value; something is missing.
What do we need to \textit{cons} atoms onto? \hspace{1cm} A list.
\begin{itemize}
\item Remember The Law of Cons.
\end{itemize}

For the purpose of \textit{consing}, what value can we give when \textit{(null? l)} is true?
\begin{itemize}
\item Since the final value must be a list, we cannot use \#t or \#f. Let's try \textit{(quote ())}.
\end{itemize}

With \textit{()} as a value, we now have three \textit{cons} steps to go back and pick up. We need to:

\begin{itemize}
\item I. \text{either}
  \begin{itemize}
  \item 1. \textit{cons e} onto \textit{()}
  \item 2. \textit{cons c} onto the value of 1
  \item 3. \textit{cons a} onto the value of 2
  \end{itemize}
\item II. \text{or}
  \begin{itemize}
  \item 1. \textit{cons a} onto the value of 2
  \item 2. \textit{cons c} onto the value of 3
  \item 3. \textit{cons e} onto \textit{()}
  \end{itemize}
\item III. \text{or}
  \begin{itemize}
  \item \textit{cons a} onto
    \begin{itemize}
    \item the \textit{cons} of \textit{c} onto
    \item the \textit{cons} of \textit{e} onto
    \item \textit{()}
    \end{itemize}
  \end{itemize}
\end{itemize}

In any case, what is the value of \textit{(firsts l)}

With which of the three alternatives do you feel most comfortable? \hspace{1cm} Correct! Now you should use that one.

What is \textit{(insertR new old lat)} where \textit{new} is topping \textit{old} is fudge and \textit{lat} is (ice cream with fudge topping for dessert).

\textit{(insertR new old lat)} where \textit{new} is jalapeño \textit{old} is and \textit{lat} is (tacos tamales and jalapeño salsa).
\[(\text{insertR } \text{new old lat})\]

where
\[\text{new is e}\]
\[\text{old is d}\]
and
\[\text{lat is (a b c d f g d h)}\]

In your own words, what does \((\text{insertR } \text{new old lat})\) do?

In our words:
"It takes three arguments: the atoms \text{new} and \text{old}, and a lat. The function \text{insertR} builds a lat with \text{new} inserted to the right of the first occurrence of \text{old}.”

See if you can write the first three lines of the function \text{insertR}

\[
\begin{align*}
\text{(define insertR} \\
\text{(lambda (new old lat) } \\
\text{(cond . . .)))}
\end{align*}
\]

Which argument changes when we recur with \text{insertR}

\text{lat}, because we can only look at one of its atoms at a time.

How many questions can we ask about the \text{lat}?

Two.

A \text{lat} is either the null list or a non-empty list of atoms.

Which questions do we ask?

First, we ask \((\text{null? lat})\). Second, we ask \text{else}, because \text{else} is always the last question.

What do we know if \((\text{null? lat})\) is not true?

We know that \text{lat} has at least one element.

Which questions do we ask about the first element?

First, we ask \((\text{eq? (car lat) old})\). Then we ask \text{else}, because there are no other interesting cases.
Now see if you can write the whole function \(\text{insertR}\).

\[
\text{(define insertR} \\
\quad \text{(lambda (new old lat)} \\
\quad \quad \text{(cond} \\
\quad \quad \quad \text{(null? lat) (quote ())} \\
\quad \quad \quad \text{else (cond} \\
\quad \quad \quad \quad \text{(eq? (car lat) old) (cons (cdr lat) (insertR new old (cdr lat))))))}))
\]

Here is our first attempt.

\[
\text{(define insertR} \\
\quad \text{(lambda (new old lat)} \\
\quad \quad \text{(cond} \\
\quad \quad \quad \text{(null? lat) (quote ())} \\
\quad \quad \quad \text{else (cond} \\
\quad \quad \quad \quad \text{(eq? (car lat) old) (cdr lat))} \\
\quad \quad \quad \text{else (cons (car lat) (insertR new old (cdr lat)))))))))
\]

What is the value of the application \(\text{(insertR new old lat)}\) that we just determined where \(\text{new}\) is topping \(\text{old}\) is fudge and \(\text{lat}\) is (ice cream with fudge for dessert).

So far this is the same as \text{rember}.

What do we do in \(\text{insertR}\) when \(\text{(eq? (car lat) old)}\) is true?

When \(\text{(car lat)}\) is the same as \text{old}, we want to insert \text{new} to the right.

How is this done?

Let’s try \text{consing new onto (cdr lat)}.

Now we have

\[
\text{(define insertR} \\
\quad \text{(lambda (new old lat)} \\
\quad \quad \text{(cond} \\
\quad \quad \quad \text{(null? lat) (quote ())} \\
\quad \quad \quad \text{else (cond} \\
\quad \quad \quad \quad \text{(eq? (car lat) old) (cons new (cdr lat)))} \\
\quad \quad \quad \text{else (cons (car lat) (insertR new old (cdr lat))))))}))
\]

Yes.
So what is \((\text{insert}R \ \text{new} \ \text{old} \ \text{lat})\) now where
new is topping
old is fudge
and
lat is (ice cream with fudge for dessert)

(ice cream with topping for dessert).

Is this the list we wanted?
No, we have only replaced fudge with topping.

What still needs to be done?
Somehow we need to include the atom that is the same as \text{old} before the atom \text{new}.

How can we include \text{old} before \text{new}
Try \textit{consing} \text{old} onto \((\text{cons} \ \text{new} \ (\text{cdr} \ \text{lat}))\).

Now let’s write the rest of the function \textit{insert}R

\begin{verbatim}
(define insertR
  (lambda (new old lat)
    (cond ((null? lat) (quote ()))
          (else (cond ((eq? (car lat) old)
                      (cons old
                          (cons new (cdr lat))))
                   (else (cons (car lat)
                                 (insertR new old
                                     (cdr lat))))))))
\end{verbatim}

When \text{new} is topping, \text{old} is fudge, and \text{lat} is (ice cream with fudge for dessert), the value of the application, \((\text{insert}R \ \text{new} \ \text{old} \ \text{lat})\), is (ice cream with fudge topping for dessert).

If you got this right, have one.
Now try \textit{insertL}

Hint: \textit{insertL} inserts the atom \textit{new} to the left of the first occurrence of the atom \textit{old} in \textit{lat}

This much is easy, right?

\begin{verbatim}
(define insertL
  (lambda (new old lat)
    (cond
      ((null? lat) (quote ()))
      (else (cond
        ((eq? (car lat) old)
         (cons new (cons old (cdr lat))))
        (else (cons (car lat)
                     (insertL new old (cdr lat))))))))
\end{verbatim}

Did you think of a different way to do it?

For example,

\begin{verbatim}
  ((eq? (car lat) old)
   (cons new (cons old (cdr lat))))
\end{verbatim}

could have been

\begin{verbatim}
  ((eq? (car lat) old)
   (cons new lat))
\end{verbatim}

since \((\text{cons old (cdr lat)})\) where \textit{old} is \textit{eq?} to \textit{(car lat)} is the same as \textit{lat}.

Now try \textit{subst}

Hint: \((\textit{subst new old lat})\) replaces the first occurrence of \textit{old} in the \textit{lat} with \textit{new}

For example,

\begin{verbatim}
  new is topping
  old is fudge
\end{verbatim}

and

\begin{verbatim}
  lat is (ice cream with fudge for dessert)
  the value is
  (ice cream with topping for dessert)
\end{verbatim}

Now you have the idea.

Obviously,

\begin{verbatim}
(define subst
  (lambda (new old lat)
    (cond
      ((null? lat) (quote ()))
      (else (cond
        ((eq? (car lat) old)
         (cons new (cdr lat))))
        (else (cons (car lat)
                     (subst new old (cdr lat)))))))
\end{verbatim}

This is the same as one of our incorrect attempts at \textit{insertR}.

\textit{Cons the Magnificent}
Go cons a piece of cake onto your mouth.

Now try \textit{subst2}

Hint:

\[(\textit{subst2 new o1 o2 lat})\]

replaces either the first occurrence of \textit{o1} or the first occurrence of \textit{o2} by \textit{new}

For example, where

\textit{new} is \textit{vanilla} \\
\textit{o1} is \textit{chocolate} \\
\textit{o2} is \textit{banana} \\
and

\textit{lat} is \((\textit{banana ice cream} \\
\textit{with chocolate topping})\)

the value is \((\textit{vanilla ice cream} \\
\textit{with chocolate topping})\)

\begin{verbatim}
(define subst2
  (lambda (new o1 o2 lat)
    (cond
      ((null? lat) (quote ()))
      (else (cond
        ((eq? (car lat) o1)
         (cons new (cdr lat))))
        ((eq? (car lat) o2)
         (cons new (cdr lat))))
        (else (cons (car lat)
          (subst2 new o1 o2 (cdr lat))))))
)
\end{verbatim}

Did you think of a better way?

Replace the two \textit{eq?} lines about the \textit{(car lat)} by

\[(\textit{or (eq? (car lat) o1) (eq? (car lat) o2)})
  (cons new (cdr lat))\].

If you got the last function, go and repeat the cake-consing.

Do you recall what \textit{rember} does?

The function \textit{rember} looks at each atom of a \textit{lat} to see if it is the same as the atom \textit{a}. If it is not, \textit{rember} saves the atom and proceeds. When it finds the first occurrence of \textit{a}, it stops and gives the value \textit{(cdr lat)}, or the rest of the \textit{lat}, so that the value returned is the original \textit{lat}, with only that occurrence of \textit{a} removed.
Write the function `multirember` which gives as its final value the list with all occurrences of `a` removed.

```scheme
(define multirember
  (lambda (a lat)
    (cond
      ((null? lat) (quote ()))
      (else
        (cond
          ((eq? (car lat) a)
            (multirember a (cdr lat)))
          (else (cons (car lat)
                        (multirember a (cdr lat))))))))
```

Hint: What do we want as the value when `(eq? (car lat) a)` is true?
Consider the example
where `a` is `cup`
and
`lat` is `(coffee cup tea cup and hick cup)`

Can you see how `multirember` works?

Possibly not, so we will go through the steps necessary to arrive at the value `(coffee tea and hick)`.  

- `(null? lat)`
  - No, so move to the next line.
- `else`
  - Yes.
- `(eq? (car lat) a)`
  - No, so move to the next line.

What is the meaning of
` cons (car lat)
  (multirember a
    (cdr lat))`

Save `(car lat)—coffee—to be consed onto the value of `(multirember a (cdr lat)) later. 
Now determine `(multirember a (cdr lat))`. 

`(null? lat)`

- No, so move to the next line.

*Cons the Magnificent*
<table>
<thead>
<tr>
<th>else</th>
<th>Naturally.</th>
</tr>
</thead>
<tbody>
<tr>
<td>(eq? (car lat) a)</td>
<td>Yes, so forget (car lat), and determine (multirember a (cdr lat)).</td>
</tr>
<tr>
<td>(null? lat)</td>
<td>No, so move to the next line.</td>
</tr>
<tr>
<td>else</td>
<td>Yes!</td>
</tr>
<tr>
<td>(eq? (car lat) a)</td>
<td>No, so move to the next line.</td>
</tr>
<tr>
<td>What is the meaning of</td>
<td>Save (car lat)—tea—to be consed onto the value of (multirember a (cdr lat)) later. Now determine (multirember a (cdr lat)).</td>

<tr>
<td>(cons (car lat)</td>
<td>(multirember a (cdr lat))))</td>
</tr>
<tr>
<td>(null? lat)</td>
<td>No, so move to the next line.</td>
</tr>
<tr>
<td>else</td>
<td>Okay, move on.</td>
</tr>
<tr>
<td>(eq? (car lat) a)</td>
<td>Yes, so forget (car lat), and determine (multirember a (cdr lat)).</td>
</tr>
<tr>
<td>(null? lat)</td>
<td>No, so move to the next line.</td>
</tr>
<tr>
<td>(eq? (car lat) a)</td>
<td>No, so move to the next line.</td>
</tr>
<tr>
<td>What is the meaning of</td>
<td>Save (car lat)—and—to be consed onto the value of (multirember a (cdr lat)) later. Now determine (multirember a (cdr lat)).</td>
</tr>
<tr>
<td>(cons (car lat)</td>
<td>(multirember a (cdr lat))))</td>
</tr>
<tr>
<td>Expression</td>
<td>Description</td>
</tr>
<tr>
<td>------------</td>
<td>-------------</td>
</tr>
<tr>
<td>(null? lat)</td>
<td>No, so move to the next line.</td>
</tr>
<tr>
<td>(eq? (car lat) a)</td>
<td>No, so move to the next line.</td>
</tr>
<tr>
<td>What is the meaning of (cons (car lat) (multirember a (cdr lat)))</td>
<td>Save (car lat)—hick—to be consed onto the value of (multirember a (cdr lat)) later. Now determine (multirember a (cdr lat)).</td>
</tr>
<tr>
<td>(null? lat)</td>
<td>No, so move to the next line.</td>
</tr>
<tr>
<td>(eq? (car lat) a)</td>
<td>Yes, so forget (car lat), and determine (multirember a (cdr lat)).</td>
</tr>
<tr>
<td>(null? lat)</td>
<td>Yes, so the value is ().</td>
</tr>
<tr>
<td>Are we finished?</td>
<td>No, we still have several conses to pick up.</td>
</tr>
<tr>
<td>What do we do next?</td>
<td>We cons the most recent (car lat) we have—hick—onto ().</td>
</tr>
<tr>
<td>What do we do next?</td>
<td>We cons and onto (hick).</td>
</tr>
<tr>
<td>What do we do next?</td>
<td>We cons tea onto (and hick).</td>
</tr>
<tr>
<td>What do we do next?</td>
<td>We cons coffee onto (tea and hick).</td>
</tr>
<tr>
<td>Are we finished now?</td>
<td>Yes.</td>
</tr>
</tbody>
</table>
Now write the function \textit{multiinsertR}

\begin{verbatim}
(define multiinsertR
  (lambda (new old lat)
    (cond
      (null? lat) ()
      (else
        (cond
          (eq? (car lat) old) (cons new (multiinsertR new old (cdr lat)))
          (else (cons (car lat) (multiinsertR new old (cdr lat)))))))))
\end{verbatim}

Is this function defined correctly?

\begin{verbatim}
(define multiinsertL
  (lambda (new old lat)
    (cond
      ((null? lat) (quote ())
      (else
        (cond
          ((eq? (car lat) old) (cons new (cons old (multiinsertL new old (cdr lat))))
          (else (cons (car lat) (multiinsertL new old (cdr lat))))))))
\end{verbatim}

Was the terminal condition ever reached?

No, because we never get past the first occurrence of \textit{old}.

It would also be correct to use \textit{old} in place of \textit{(car lat)} because we know that \textit{(eq? (car lat) old)}.

Not quite. To find out why, go through \textit{(multiinsertL new old lat)} where
\begin{itemize}
  \item \textit{new} is fried
  \item \textit{old} is fish
  \item \textit{lat} is \textit{(chips and fish or fish and fried)}.
\end{itemize}
Now, try to write the function \texttt{multiinsertL} again:

\begin{verbatim}
(define multiinsertL
  (lambda (new old lat)
    (cond
      (<--
        (else
          (cond
            (null? lat)
            (quote ())
          (else
            (cond
              ((eq? (car lat) old)
                (cons new
                  (cons old
                    (multiinsertL new old
                      (cdr lat))))))
            (else
              (cons (car lat)
                (multiinsertL new old
                  (cdr lat))))))))))
\end{verbatim}

The Fourth Commandment

\textit{(preliminary)}

Always change at least one argument while recurring. It must be changed to be closer to termination. The changing argument must be tested in the termination condition: when using \texttt{cdr}, test termination with \texttt{null?}.

Now write the function \texttt{multisubst}

\begin{verbatim}
(define multisubst
  (lambda (new old lat)
    (cond
      (<--
        (else
          (cond
            (null? lat)
            (quote ())
          (else
            (cond
              ((eq? (car lat) old)
                (cons new
                  (multisubst new old
                    (cdr lat))))))
            (else
              (cons (car lat)
                (multisubst new old
                  (cdr lat))))))))))
\end{verbatim}
4. Numbers Games
<table>
<thead>
<tr>
<th>Question</th>
<th>Answer</th>
</tr>
</thead>
<tbody>
<tr>
<td>Is 14 an atom?</td>
<td>Yes, because all numbers are atoms.</td>
</tr>
<tr>
<td>Is ((\text{atom? ~} n)) true or false where (n) is 14</td>
<td>True, because 14 is an atom.</td>
</tr>
<tr>
<td>Is (-3) a number?</td>
<td>Yes, but we do not consider negative numbers.</td>
</tr>
<tr>
<td>Is 3.14159 a number?</td>
<td>Yes, but we consider only whole numbers.</td>
</tr>
<tr>
<td>Are (-3) and 3.14159 numbers?</td>
<td>Yes, but the only numbers we use are the nonnegative integers (i.e., 0, 1, 2, 3, 4, ...).</td>
</tr>
</tbody>
</table>

What is \((\text{add1}^1 ~ n)\) where \(n\) is 67

\[68.\]

\[\text{L: \text{add1}}\]
\[\text{S: (define add1}
\[\quad \text{(lambda (n)}
\[\quad \quad (+ n 1))))\]

What is \((\text{add1} ~ 67)\)

Also 68, because we don’t need to say “where \(n\) is 67” when the argument is a number.

What is \((\text{sub1}^1 ~ n)\) where \(n\) is 5

\[4.\]

\[\text{L: \text{sub1}}\]
\[\text{S: (define sub1}
\[\quad \text{(lambda (n)}
\[\quad \quad (- n 1))))\]
What is \((\text{sub1} \ 0)\)  

No answer.\(^1\)

\(^1\) \((\text{sub1} \ n)\), where \(n\) is 0, has no answer because we consider only nonnegative numbers. In practice, this result is -1.

Is \((\text{zero?} \ 0)\) true or false?  

True.

\(^{1}\) L: \text{zerop}

Is \((\text{zero?} \ 1492)\) true or false?  

False.

What is \((+ \ 46 \ 12)\)  

58.

Try to write the function \(+\)  

Hint: It uses \(\text{zero?} \ \text{add1}^{1}\) and \(\text{sub1}^{1}\)

\[(\text{define } +^{1}  
(\lambda (n \ m)  
(\text{cond}  
((\text{zero?} \ m) \ n)  
(\text{else} (\text{add1} (+ n (\text{sub1} m))))))))\]

Wasn’t that easy?

\(^1\) Remember to use our definitions for \text{add1} and \text{sub1}.

But didn’t we just violate The First Commandment?  

Yes, but we can treat \text{zero?} like \text{null?} since \text{zero?} asks if a number is empty and \text{null?} asks if a list is empty.

If \text{zero?} is like \text{null?}  

\text{is add1 like cons}  

Yes! \text{cons} builds lists and \text{add1} builds numbers.
What is \((-14 \ 3)\)

What is \((-17 \ 9)\)

What is \((-18 \ 25)\)

No answer. There are no negative numbers.

Try to write the function \(-\)

Hint: Use \textit{sub1}

How about this:

\[
(\text{define } -^1
\quad (\text{lambda } (n \ m)
\quad (\text{cond}
\quad \quad ((\text{zero? } m) \ n)
\quad \quad (\text{else} \ (\text{sub1} (- n (\text{sub1 } m))))))
\]

\[\]

1 L, S: This is like \(-\). Write it as \textit{o-} (see preface).

Can you describe how \((-n \ m)\) works?

It takes two numbers as arguments, and reduces the second until it hits zero. It subtracts one from the result as many times as it did to cause the second one to reach zero.

Is this a tup?

\((2 \ 11 \ 3 \ 79 \ 47 \ 6)\)

Yes: tup is short for tuple.

Is this a tup?

\((8 \ 55 \ 5 \ 555)\)

Yes, of course, it is also a list of numbers.

Is this a tup?

\((1 \ 2 \ 8 \ \text{apple} \ 4 \ 3)\)

No, it is just a list of atoms.

Is this a tup?

\((3 \ (7 \ 4) \ 13 \ 9)\)

No, because it is not a list of numbers. \((7 \ 4)\) is not a number.
<table>
<thead>
<tr>
<th>Question</th>
<th>Answer</th>
</tr>
</thead>

<td>Two.</td>
</tr>
</tbody>
</table>

*Numbers Games*
The First Commandment
(first revision)

When recurring on a list of atoms, \( lat \), ask two questions about it: \( \text{null? lat} \) and else.
When recurring on a number, \( n \), ask two questions about it: \( \text{zero? n} \) and else.

What does \( \text{cons} \) do?  It builds lists.

What does \( \text{addtup} \) do?  It builds a number by totaling all the numbers in a tup.

What is the terminal condition line of \( \text{addtup} \)?  \( \text{((null? tup) 0)}. \)

What is the natural recursion for \( \text{addtup} \)?  \( \text{(addtup (cdr tup))}. \)

What does \( \text{addtup} \) use to build a number?  It uses \( + \), because \( + \) builds numbers, too!

Fill in the dots in the following definition:

\[
\text{(define addtup}
\begin{array}{l}
\text{(lambda (tup)}
\text{(cond)}
\text{((null? tup) 0)}
\text{(else ...)))}
\end{array}
\]

Here is what we filled in:
\( (+ \text{(car tup)} \text{(addtup (cdr tup))}). \)
Notice the similarity between this line, and the last line of the function \( \text{remer}: \)
\( \text{(cons (car lat) (remer a (cdr lat))}). \)

What is \(( \times 5 3)\)  15.

What is \(( \times 13 4)\)  52.
What does \((\times n m)\) do?  It builds up a number by adding \(n\) up \(m\) times.

What is the terminal condition line for \(\times\) \(\((\text{zero} m) 0)\), because \(n \times 0 = 0\).

Since \((\text{zero} m)\) is the terminal condition, \(m\) must eventually be reduced to zero. What function is used to do this?

The Fourth Commandment

(first revision)

Always change at least one argument while recurring. It must be changed to be closer to termination. The changing argument must be tested in the termination condition:

when using \(\text{cdr}\), test termination with \(\text{null}\?) and
when using \(\text{sub1}\), test termination with \(\text{zero}\?)

What is another name for \((\times n (\text{sub1} m))\) in this case?

It's the natural recursion for \(\times\).

Try to write the function \(\times\)

\[
\begin{align*}
(\text{define} &\times^1 \\
{\text{lambda} (n m) } &\ (\text{cond} \ \\
{\quad ((\text{zero} m) 0) } &\ (\text{else} (n \ (\times (\text{sub1} m)))))
\end{align*}
\]

\(^1\) L, S: This is like \(*\)
<table>
<thead>
<tr>
<th>Question</th>
<th>Answer</th>
</tr>
</thead>
<tbody>
<tr>
<td>What is (( \times 12 3 ))</td>
<td>36, but let’s follow through the function one time to see how we get this value.</td>
</tr>
<tr>
<td>((\text{zero? } m))</td>
<td>No.</td>
</tr>
<tr>
<td>What is the meaning of ((\oplus n (\times n (\text{sub1} m))))</td>
<td>It adds (n) (where (n = 12)) to the natural recursion. If (\times) is correct then ((\times 12 (\text{sub1} 3))) should be 24.</td>
</tr>
<tr>
<td>What are the new arguments of ((\times n m))</td>
<td>(n) is 12, and (m) is 2.</td>
</tr>
<tr>
<td>((\text{zero? } m))</td>
<td>No.</td>
</tr>
<tr>
<td>What is the meaning of ((\oplus n (\times n (\text{sub1} m))))</td>
<td>It adds (n) (where (n = 12)) to ((\times n (\text{sub1} m))).</td>
</tr>
<tr>
<td>What are the new arguments of ((\times n m))</td>
<td>(n) is 12, and (m) is 1.</td>
</tr>
<tr>
<td>((\text{zero? } m))</td>
<td>No.</td>
</tr>
<tr>
<td>What is the meaning of ((\oplus n (\times n (\text{sub1} m))))</td>
<td>It adds (n) (where (n = 12)) to ((\times n (\text{sub1} m))).</td>
</tr>
<tr>
<td>What is the value of the line ((\text{zero? } m) 0))</td>
<td>0, because ((\text{zero? } m)) is now true.</td>
</tr>
<tr>
<td>Are we finished yet?</td>
<td>No.</td>
</tr>
</tbody>
</table>

Chapter 4
Why not?  
Because we still have three +es to pick up.

What is the value of the original application?  
Add 12 to 12 to 12 to 0 yielding 36,  
Notice that \( n \) has been +ed \( m \) times.

Argue, using equations, that \( \times \) is the  
conventional multiplication of nonnegative  
terms, where \( n \) is 12 and \( m \) is 3.  
\[
(\times 12 3) = 12 + (\times 12 2) \\
= 12 + 12 + (\times 12 1) \\
= 12 + 12 + 12 + (\times 12 0) \\
= 12 + 12 + 12 + 0,
\]
which is as we expected. This technique 
works for all recursive functions, not just 
those that use numbers. You can use this 
approach to write functions as well as to 
argue their correctness.

Again, why is 0 the value for the terminal  
condition line in \( \times \)  
Because 0 will not affect +. That is,  
\[ n + 0 = n. \]

---

**The Fifth Commandment**

When building a value with \( \div \), always use 0 for the value of the 
terminating line, for adding 0 does not change the value of an  
addition.

When building a value with \( \times \), always use 1 for the value of the 
terminating line, for multiplying by 1 does not change the value 
of a multiplication.

When building a value with \texttt{cons}, always consider () for the value  
of the terminating line.

---

What is \( (tup + tup1 + tup2) \)  
where  
\( tup1 \) is (3 6 9 11 4)  
and  
\( tup2 \) is (8 5 2 0 7)  
\( (11 11 11 11 11). \)

---

*Numbers Games*
What is \((tup+\ tup1\ tup2)\) where \\
\(tup1\) is \((2\ 3)\) \\
and \\
\(tup2\) is \((4\ 6)\)

What does \((tup+\ tup1\ tup2)\) do? 

It adds the first number of \(tup1\) to the first number of \(tup2\), then it adds the second number of \(tup1\) to the second number of \(tup2\), and so on, building a tup of the answers, for tups of the same length.

What is unusual about \(tup+\)?

It looks at each element of two tups at the same time, or in other words, it recurs on two tups.

If you recur on one tup how many questions do you have to ask?

Two, they are \((null?\ tup)\) and else.

When recurring on two tups, how many questions need to be asked about the tups?

Four: if the first tup is empty or non-empty, and if the second tup is empty or non-empty.

Do you mean the questions \\
\((and\ (null?\ tup1)\ (null?\ tup2))\) \\
\((null?\ tup1)\) \\
\((null?\ tup2)\) \\
and \\
else

Yes.

Can the first \(tup\) be \((\)\) at the same time as the second is other than \((\)\)?

No, because the tups must have the same length.

Does this mean \\
\((and\ (null?\ tup1)\ (null?\ tup2))\) \\
and \\
else

are the only questions we need to ask?

Yes, because \((null?\ tup1)\) is true exactly when \((null?\ tup2)\) is true.
Write the function $tup+$

$(\text{define } tup+  \\
  (\text{lambda} (\text{tup1} \text{ tup2})  \\
  (\text{cond}  \\
     ((\text{and} (\text{null? tup1}) (\text{null? tup2}))  \\
      (\text{quote} ()))  \\
     (\text{else}  \\
      (\text{cons} (\text{+} (\text{car} \text{ tup1}) (\text{car} \text{ tup2}))  \\
      (tup+  \\
      (\text{cdr} \text{ tup1}) (\text{cdr} \text{ tup2}))))))))$

---

What are the arguments of $+$ in the last line?

$(\text{car} \text{ tup1})$ and $(\text{car} \text{ tup2})$.

---

What are the arguments of $\text{cons}$ in the last line?

$(\text{+} (\text{car} \text{ tup1}) (\text{car} \text{ tup2}))$ and $(tup+ (\text{cdr} \text{ tup1}) (\text{cdr} \text{ tup2}))$.

---

What is $(tup+ \text{ tup1} \text{ tup2})$ where $\text{tup1}$ is $(3 \ 7)$ and $\text{tup2}$ is $(4 \ 6)$?

$(7 \ 13)$. But let’s see how it works.

---

$(\text{null? tup1})$

No.

---

$(\text{cons}  \\
  (\text{+} (\text{car} \text{ tup1}) (\text{car} \text{ tup2}))  \\
  (tup+ (\text{cdr} \text{ tup1}) (\text{cdr} \text{ tup2})))$

$\text{cons}$ $7$ onto the natural recursion: $(tup+ (\text{cdr} \text{ tup1}) (\text{cdr} \text{ tup2}))$.

---

Why does the natural recursion include the $\text{cdr}$ of both arguments?

Because the typical element of the final value uses the $\text{car}$ of both tups, so now we are ready to consider the rest of both tups.

---

$(\text{null? tup1})$

No.

---

$(\text{null? tup1})$

where $\text{tup1}$ is now $(7)$ and $\text{tup2}$ is now $(6)$
\[
(\text{cons} \\
\quad (\uplus (\text{car} \ \text{tup1}) (\text{car} \ \text{tup2})) \\
\quad (\text{tup+} (\text{cdr} \ \text{tup1}) (\text{cdr} \ \text{tup2})))
\]

\[
(\text{null?} \ \text{tup1})
\]

Then, what must be the value? \(((), \text{because (null? \ tup2) must be true.})\)

What is the value of the application? \((7 \ 13). \text{That is, the cons of 7 onto the cons of 13 onto (}).\)

What problem arises when we want \((\text{tup+} \ \text{tup1} \ \text{tup2})\) where \(\text{tup1}\) is \((3 \ 7)\) and \(\text{tup2}\) is \((4 \ 6 \ 8 \ 1)\)

No answer, since \(\text{tup1}\) will become null before \(\text{tup2}\).

See The First Commandment: We did not ask all the necessary questions!

But, we would like the final value to be \((7 \ 13 \ 8 \ 1)\).

Can we still write \(\text{tup+}\) even if the tups are not the same length? \(\text{Yes!}\)

What new terminal condition line can we add to get the correct final value? Add \((\text{null?} \ \text{tup1} \ \text{tup2}).\)

What is \((\text{tup+} \ \text{tup1} \ \text{tup2})\) where \(\text{tup1}\) is \((3 \ 7 \ 8 \ 1)\) and \(\text{tup2}\) is \((4 \ 6)\)

No answer, since \(\text{tup2}\) will become null before \(\text{tup1}\).

See The First Commandment: We did not ask all the necessary questions!

What do we need to include in our function? We need to ask two more questions:
\((\text{null?} \ \text{tup1}) \text{ and (null? \ tup2)}.\)

What does the second new line look like? \((\text{null?} \ \text{tup2}) \ \text{tup1}).\)
Here is a definition of \( \text{tup}^+ \) that works for any two tups:

\[
\begin{align*}
\text{(define \text{tup}+} & \quad \text{(lambda (tup1 tup2)} \\
& \quad \text{(cond)} \\
& \quad \text{((and (null? tup1) (null? tup2)) (quote ()))} \\
& \quad ((null? tup1) tup2) \\
& \quad ((null? tup2) tup1) \\
& \quad \text{(else)} \\
& \quad \text{(cons (+ (car tup1) (car tup2)) (tup+ (cdr tup1) (cdr tup2))))})
\end{align*}
\]

Can you simplify it?

\[
\begin{align*}
\text{(define \text{tup}+} & \quad \text{(lambda (tup1 tup2)} \\
& \quad \text{(cond)} \\
& \quad \text{((null? tup1) tup2)} \\
& \quad \text{((null? tup2) tup1)} \\
& \quad \text{(else)} \\
& \quad \text{(cons (+ (car tup1) (car tup2)) (tup+ (cdr tup1) (cdr tup2))))})
\end{align*}
\]

Does the order of the two terminal conditions matter? No.

Is \textbf{else} the last question? Yes, because either \((\text{null? tup1})\) or \((\text{null? tup2})\) is true if either one of them does not contain at least one number.

What is \( (> \ 12 \ 133) \)? \#f—false.

What is \( (> \ 120 \ 11) \)? \#t—true.

On how many numbers do we have to recur? Two, \( n \) and \( m \).

How do we recur? With \((\text{sub1 } n)\) and \((\text{sub1 } m)\).

When do we recur? When we know neither number is equal to 0.

How many questions do we have to ask about \( n \) and \( m \)? Three: \((\text{zero? } n)\), \((\text{zero? } m)\), and \textbf{else}.

\textbf{Numbers Games}
Can you write the function > now using zero? and sub1

How about

\[
\text{(define >}
\begin{align*}
\text{(lambda } (n \ m) \\
\text{(cond } \\
& ((\text{zero? } m) \ #t) \\
& ((\text{zero? } n) \ #f) \\
& \text{else } (> (\text{sub1 } n) (\text{sub1 } m)))))
\end{align*}
\]

Is the way we wrote (> n m) correct?

No, try it for the case where n and m are the same number. Let n and m be 3.

\(\text{(zero? 3)}\)

No, so move to the next question.

\(\text{(zero? 3)}\)

No, so move to the next question.

What is the meaning of (> (sub1 n) (sub1 m))

Recur, but with both arguments reduced by one.

\(\text{(zero? 2)}\)

No, so move to the next question.

\(\text{(zero? 2)}\)

No, so move to the next question.

What is the meaning of (> (sub1 n) (sub1 m))

Recur, but with both arguments closer to zero by one.

\(\text{(zero? 1)}\)

No, so move to the next question.

\(\text{(zero? 1)}\)

No, so move to the next question.

What is the meaning of (> (sub1 n) (sub1 m))

Recur, but with both arguments reduced by one.
(zero? 0) Yes, so the value of (> n m) is #t.

Is this correct? No, because 3 is not greater than 3.

Does the order of the two terminal conditions matter? Think about it.

Does the order of the two terminal conditions matter? Try it out!

Does the order of the two previous answers matter? Yes. Think first, then try.

How can we change the function > to take care of this subtle problem? Switch the zero? lines:

```
(define >
  (lambda (n m)
    (cond
      ((zero? n) #f)
      ((zero? m) #t)
      (else (> (sub1 n) (sub1 m))))))
```

What is (< 4 6) #t.

(< 8 3) #f.

(< 6 6) #f.

Now try to write <

```
(define <
  (lambda (n m)
    (cond
      ((zero? m) #f)
      ((zero? n) #t)
      (else (< (sub1 n) (sub1 m))))))
```
Here is the definition of =

```
(define =
  (lambda (n m)
    (cond
      ((zero? m) (zero? n))
      ((zero? n) #f)
      (else (= (sub1 n) (sub1 m))))))
```

Rewrite = using < and >

Does this mean we have two different functions for testing equality of atoms?

Yes, they are = for atoms that are numbers and eq? for the others.

```
(τ 1 1)
```

1.

```
(τ 2 3)
```

8.

```
(τ 5 3)
```

125.

Now write the function τ

Hint: See the The First and Fifth Commandments.

```
(define ↑¹
  (lambda (n m)
    (cond
      ((zero? m) 1)
      (else (× n (↑ n (sub1 m)))))))
```

What is a good name for this function?

We have never seen this kind of definition before; the natural recursion also looks strange.

```
(define ???
  (lambda (n m)
    (cond
      ((< n m) 0)
      (else (add1 (??? (= n m m)))))))
```

1 L, S: This is like expt.
<table>
<thead>
<tr>
<th>Question</th>
<th>Answer</th>
</tr>
</thead>
<tbody>
<tr>
<td>What does the first question check?</td>
<td>It determines whether the first argument is less than the second one.</td>
</tr>
<tr>
<td>And what happens in the second line?</td>
<td>We recur with a first argument from which we subtract the second argument. When the function returns, we add 1 to the result.</td>
</tr>
<tr>
<td>So what does the function do?</td>
<td>It counts how many times the second argument fits into the first one.</td>

|                                                              | (define \(\text{\(\frac{1}{1}\)}\))
|                                                              | (lambda (n m)
|                                                              | (cond
|                                                              | ((< n m) 0)
|                                                              | (else (add1 (\(\frac{1}{1}\) (- n m) m))))))
| What is \(\frac{15}{4}\)                                     | Easy, it is 3.                                                        |
| How do we get there?                                         | Easy, too:                                                             |
|                                                              | \(\left(\frac{15}{4}\right) = 1 + \left(\frac{11}{4}\right)\)       |
|                                                              | = 1 + (1 + (\(\frac{7}{4}\)))                                        |
|                                                              | = 1 + (1 + (1 + (\(\frac{3}{4}\))))                                 |
|                                                              | = 1 + (1 + (1 + 0)).                                                 |
| Wouldn’t a (ham and cheese on rye) be good right now?         |                                                                        |
| Don’t forget the mustard!                                    |                                                                        |
What is the value of \( \text{length lat} \)
where
\[ \text{lat} \text{ is (hotdogs with mustard sauerkraut and pickles)} \]

What is \( \text{length lat} \)
where
\[ \text{lat} \text{ is (ham and cheese on rye)} \]

Now try to write the function \text{length}:

\[
\text{(define length (lambda (lat) (cond ((null? lat) 0) (else (add1 (length (cdr lat)))))))}
\]

What is \( \text{pick n lat} \)
where \( n \) is 4
and
\[ \text{lat} \text{ is (lasagna spaghetti ravioli macaroni meatball)} \]

What is \( \text{pick 0 lat} \)
where \( \text{lat} \) is (a)

No answer.

Try to write the function \text{pick}:

\[
\text{(define pick (lambda (n lat) (cond ((zero? (sub1 n)) (car lat)) (else (pick (sub1 n) (cdr lat))))))}
\]

What is \( \text{rempick n lat} \)
where \( n \) is 3
and
\[ \text{lat} \text{ is (hotdogs with hot mustard)} \]
Now try to write `rempick`

Is `(number? a)` true or false where `a` is tomato

False.

Is `(number? 76)` true or false?

True.

Can you write `number?` which is true if its argument is a numeric atom and false if it is anything else?

No: `number?`, like `add1`, `sub1`, `zero?`, `car`, `cdr`, `cons`, `null?`, `eq?`, and `atom?`, is a primitive function.

Now using `number?` write the function `no-nums` which gives as a final value a list obtained by removing all the numbers from the list. For example, where `lat` is `(5 pears 6 prunes 9 dates)` the value of `(no-nums lat)` is `(pears prunes dates)`

```
(define no-nums
  (lambda (lat)
    (cond
      ((null? lat) (quote ()))
      (else (cond
              ((number? (car lat))
               (no-nums (cdr lat)))
              (else (cons (car lat)
                           (no-nums (cdr lat))))))))
```

Numbers Games
Now write \textit{all-nums} which extracts a tup from a lat using all the numbers in the lat.

\begin{verbatim}
(define all-nums
  (lambda (lat)
    (cond
      ((null? lat) (quote ()))
      (else
        (cond
          ((number? (car lat))
            (cons (car lat)
              (all-nums (cdr lat))))
          (else (all-nums (cdr lat))))))))
\end{verbatim}

Write the function \textit{eqan?} which is true if its two arguments \((a1\) and \(a2\)) are the same atom. Remember to use = for numbers and eq? for all other atoms.

\begin{verbatim}
(define eqan?
  (lambda (a1 a2)
    (cond
      ((and (number? a1) (number? a2))
        (= a1 a2))
      ((or (number? a1) (number? a2)) #f)
      (else (eq? a1 a2))))
\end{verbatim}

Can we assume that all functions written using eq? can be generalized by replacing eq? by eqan?\textit{?}

Yes, except, of course, for \textit{eqan?} itself.

Now write the function \textit{occur} which counts the number of times an atom \(a\) appears in a lat.

\begin{verbatim}
(define occur
  (lambda (a lat)
    (cond
      ((null? lat) 0)
      (else
        (cond
          ((eq? (car lat) a)
            (add1 (occur a (cdr lat))))
          (else (occur a (cdr lat))))))))
\end{verbatim}

Chapter 4
Write the function \texttt{one?} where \texttt{(one? n)} is \#t if \(n\) is 1 and \#f (i.e., false) otherwise.

\begin{verbatim}
(define one?
  (lambda (n)
    (cond
      ((zero? n) #f)
      (else (zero? (sub1 n))))))

or

(define one?
  (lambda (n)
    (cond
      (else (= n 1)))))
\end{verbatim}

Guess how we can further simplify this function, making it a one-liner.

By removing the \texttt{(cond \ldots)} clause:

\begin{verbatim}
(define one?
  (lambda (n)
    (= n 1)))
\end{verbatim}

Now rewrite the function \texttt{rempick} that removes the \(n\)th atom from a \texttt{lat}. For example, where

\begin{verbatim}
    n is 3
\end{verbatim}

and

\begin{verbatim}
    lat is (lemon meringue salty pie)
\end{verbatim}

the value of \texttt{(rempick n lat)} is

\begin{verbatim}
    (lemon meringue pie)
\end{verbatim}

Use the function \texttt{one?} in your answer.
5.
"Oh My Gawd":
It's Full of Stars
What is \((rember\* a \, l)\)
where \(a\) is cup
and
\(l\) is \(((\text{coffee}) \, \text{cup})\)
\(\text{and} \, ((\text{tea}) \, \text{cup})\)

"\(rember\*\)" is pronounced "rember-star."

What is \((rember\* a \, l)\)
where \(a\) is sauce
and
\(l\) is \(((\text{tomato sauce})\)
\(\text{and} \, ((\text{bean}) \, \text{sauce})\)

Now write \(rember\*\)
Here is the skeleton:

\[
\begin{align*}
(\text{define} & \, \text{rember}\* \\
(\text{lambda} \, (a \, l) & ) \\
(\text{cond} & ) \\
(\text{null?} \, l & ) (\text{quote} \, ()) \\
(\text{atom?} \, (\text{car} \, l) & ) \\
(\text{cond} & ) \\
(\text{eq?} \, (\text{car} \, l) \, a & ) \\
(\text{rember}\* \, a \, (\text{cdr} \, l)) & ) \\
(\text{else} \, (\text{cons} \, (\text{car} \, l) & ) \\
(\text{rember}\* \, a \, (\text{cdr} \, l))) & ) \\
(\text{else} \, (\text{cons} \, (\text{rember}\* \, a \, (\text{car} \, l) & ) \\
(\text{rember}\* \, a \, (\text{cdr} \, l)))) & )
\end{align*}
\]

Using arguments from one of our previous examples, follow through this to see how it works. Notice that now we are recurring down the \text{car} of the list, instead of just the \text{cdr} of the list.

\((\text{lat?} \, l)\)
where
\(l\) is \(((\text{tomato sauce}))\)
\(\text{and} \, ((\text{bean}) \, \text{sauce})\)

\#f.

*Oh My Gawd*: It’s Full of Stars
Is \((\text{car } l)\) an atom
where
\(l\) is
\(((\text{tomato sauce}))\)
\(((\text{bean}) \text{ sauce})\)
\(((\text{flying}) \text{ sauce})\)

No.

What is \((\text{insert}\!R\!\times \text{ new old } l)\)
where
\(\text{new}\) is roast
\(\text{old}\) is chuck
and
\(l\) is
\(((\text{how much (wood)})\)
\(((\text{a (wood) chuck})\)
\(((\text{chuck})\))
\(((\text{if (a (wood chuck)})\))
\(((\text{could chuck wood})\))

\(((\text{how much (wood)})\)
\(((\text{a (wood) chuck roast})\)
\(((\text{chuck roast})\))
\(((\text{if (a (wood chuck roast)})\))
\(((\text{could chuck roast wood})\))

Now write the function \(\text{insert}\!R\!\times\) which
inserts the atom \(\text{new}\) to the right of \(\text{old}\)
regardless of where \(\text{old}\) occurs.

\[
\text{(define insert}\!R\!\times\!\ (}\lambda (\text{new old } l)\)
\text{(cond}
\quad (\text{(null? } l)) \text{ (quote ()})
\quad ((\text{atom? } (\text{car } l))\)
\quad (\text{(cond}
\quad \quad (\text{(eq? } (\text{car } l) \text{ old}))
\quad \quad (\text{cons old})
\quad \quad (\text{cons new}
\quad \quad \quad (\text{insert}\!R\!\times \text{ new old}
\quad \quad \quad \quad (\text{cdr } l))))))
\quad (\text{else (cons (car } l))
\quad \quad (\text{insert}\!R\!\times \text{ new old}
\quad \quad \quad (\text{cdr } l))))))
\quad (\text{else (cons (insert}\!R\!\times \text{ new old}
\quad \quad \quad (\text{car } l))
\quad \quad \quad (\text{insert}\!R\!\times \text{ new old}
\quad \quad \quad \quad (\text{cdr } l))))))\)
\text{)}
\]

Each function asks three questions.
The First Commandment

(final version)

When recurring on a list of atoms, \textit{lat}, ask two questions about it: \((\text{null? lat})\) and else.
When recurring on a number, \textit{n}, ask two questions about it: \((\text{zero? n})\) and else.
When recurring on a list of S-expressions, \textit{l}, ask three question about it: \((\text{null? l}), (\text{atom? (car l)}), \text{and else.}\)

---

<table>
<thead>
<tr>
<th>How are \textit{insertR*} and \textit{rember*} similar?</th>
<th>Each function recurs on the \textit{car} of its argument when it finds out that the argument’s \textit{car} is a list.</th>
</tr>
</thead>
<tbody>
<tr>
<td>How are \textit{rember*} and \textit{multirember} different?</td>
<td>The function \textit{multirember} does not recur with the \textit{car}. The function \textit{rember*} recurs with the \textit{car} as well as with the \textit{cdr}. It recurs with the \textit{car} when it finds out that the \textit{car} is a list.</td>
</tr>
<tr>
<td>How are \textit{insertR*} and \textit{rember*} similar?</td>
<td>They both recur with the \textit{car}, whenever the \textit{car} is a list, as well as with the \textit{cdr}.</td>
</tr>
<tr>
<td>How are all *-functions similar?</td>
<td>They all ask three questions and recur with the \textit{car} as well as with the \textit{cdr}, whenever the \textit{car} is a list.</td>
</tr>
</tbody>
</table>
| Why? | Because all *-functions work on lists that are either  
| | — empty,  
| | — an atom \textit{consed} onto a list, or  
| | — a list \textit{consed} onto a list. |

*Oh My Gawd*: It’s Full of Stars
The Fourth Commandment

(final version)

Always change at least one argument while recurring. When recurring on a list of atoms, lat, use \((cdr \text{ lat})\). When recurring on a number, \(n\), use \((sub1 \text{ n})\). And when recurring on a list of S-expressions, \(l\), use \((\text{car } l)\) and \((\text{cdr } l)\) if neither \((\text{null? } l)\) nor \((\text{atom? } (\text{car } l))\) are true.

It must be changed to be closer to termination. The changing argument must be tested in the termination condition:

when using \(cdr\), test termination with \(\text{null?}\) and
when using \(sub1\), test termination with \(\text{zero?}\).

\((\text{occursomething } a \text{ l})\)
where
\(a\) is banana
and
\(l\) is \(((\text{banana})\)
  \(((\text{split } (((\text{banana ice})))\)
    \(\text{cream } (\text{banana})\)
    \text{sherbet}))\)
\(\text{banana}\)
\(\text{bread}\)
\(\text{banana brandy})\)

What is a better name for
\(\text{occursomething}\)

\(occur^*\).
Write `occur*`

```lisp
(define occur*
  (lambda (a l)
    (cond
      (null? l) 0
      ((atom? (car l))
        (cond
          (eq? (car l) a)
          (add1 (occur* a (cdr l))))
        (else (occur* a (cdr l))))
      (else (+ (occur* a (car l))
               (occur* a (cdr l))))))
)
```

`(subst* new old l)`

where

- `new` is orange
- `old` is banana

and

- `l` is `((banana)
  (split (((banana ice)))
   (cream (banana))
   sherbet))`
- `(banana)
  (bread)
  (banana brandy))`

Write `subst*`

```lisp
(define subst*
  (lambda (new old l)
    (cond
      (null? l) (quote ()))
      ((atom? (car l))
        (cond
          (eq? (car l) old)
          (cons new
            (subst* new old (cdr l))))
        (else (cons (car l)
                    (subst* new old (cdr l)))))
      (else
       (cons (subst* new old (car l))
             (subst* new old (cdr l))))))
)
```

*Oh My Gawd*: It's Full of Stars
What is \((\text{insertL}^* \ \text{new} \ \text{old} \ l)\) where 
\new is pecker 
\old is chuck 
and 
\l is \((\text{how much} \ \text{wood})\) 
could 
\((\text{a (wood) chuck})\) 
\((\text{chuck})\) 
\((\text{if (a (wood chuck)})\) 
could chuck wood) 

\((\text{how much} \ \text{wood})\) 
could 
\((\text{a (wood) pecker chuck})\) 
\((\text{pecker chuck})\) 
\((\text{if (a (wood pecker chuck)})\) 
could pecker chuck wood).

Write \text{insertL}^* 

\begin{verbatim}
(define insertL*
  (lambda (new old l)
    (cond
     (null? l) (quote ())
     ((atom? (car l))
      (cond
       (eq? (car l) old)
       (cons new
        (cons old
         (insertL* new old
          (cdr l)))))
      (else (cons (car l)
        (insertL* new old
          (cdr l)))))
     (else (cons (insertL* new old
          (car l))
        (insertL* new old
          (cdr l)))))))
\end{verbatim}

\((\text{member}\ ^* \ a \ l)\) 
where \a is chips 
and 
\l is \((\text{potato}) \ (\text{chips ((with) fish) (chips)})\)

\#t, because the atom chips appears in the list \l.
Write $member^*$

\[
\text{(define member* (lambda (a l)) (cond \\
\hline
\text{null? l} & \#f \\
\text{atom? (car l)} & \text{or (eq? (car l) a) (member* a (cdr l)))} \\
\text{else} & \text{(member* a (cdr l)))}} \\
\hline
\]

What is $(member^* a l)$
where
   $a$ is chips
and
   $l$ is $((\text{potato} \ (\text{chips (with) fish}) \ (\text{chips}))$)

Which chips did it find?

Which chips did it find?

What is $(\text{leftmost } l)$
where
   $l$ is $((\text{potato} \ (\text{chips (with) fish}) \ (\text{chips}))$

What is $(\text{leftmost } l)$
where
   $l$ is $((\text{hot} \ (\text{tuna (and)}) \ \text{cheese})$

What is $(\text{leftmost } l)$
where
   $l$ is $(((\text{four}) \ 17 \ (\text{seventeen}))$

What is $(\text{leftmost} \ (\text{quote} ()))$

Can you describe what $\text{leftmost}$ does?

Here is our description:
"The function $\text{leftmost}$ finds the leftmost atom in a non-empty list of S-expressions that does not contain the empty list."

*Oh My Gawd*: It’s Full of Stars

87
Is `leftmost` a *-function?

It works on lists of S-expressions, but it only recurs on the `car`.

Does `leftmost` need to ask questions about all three possible cases?

No, it only needs to ask two questions. We agreed that `leftmost` works on non-empty lists that don't contain empty lists.

Now see if you can write the function `leftmost`

```
(define leftmost
  (lambda (l)
    (cond
      (atom? (car l)) (car l)
      (else (leftmost (car l))))))
```

Do you remember what `(or ...)` does?

`(or ...)` asks questions one at a time until it finds one that is true. Then `(or ...)` stops, making its value true. If it cannot find a true argument, the value of `(or ...)` is false.

What is `(and (atom? (car l)) (eq? (car l) x))` where

- `x` is pizza
- and `l` is `(mozzarella pizza)`

#f.

Why is it false?

Since `(and ...)` asks `(atom? (car l))`, which is true, it then asks `(eq? (car l) x)`, which is false; hence it is #f.
What is 
(\textbf{and} (\texttt{atom? (car l)})
\hspace{1cm}
(\texttt{eq? (car l) x}))
where
\hspace{1cm}x \text{ is pizza}
and
\hspace{1cm}l \text{ is } ((\texttt{mozzarella mushroom}) \text{ pizza})

Why is it false? 
Since \textbf{(and \ldots)} asks (\texttt{atom? (car l)}), and
\hspace{1cm}(\texttt{car l}) \text{ is not an atom}; so it is \texttt{#f}.

Give an example for \textit{x} and \textit{l} where
(\textbf{and} (\texttt{atom? (car l)})
\hspace{1cm}
(\texttt{eq? (car l) x}))
is true.
Here's one:
\hspace{1cm}x \text{ is pizza}
and
\hspace{1cm}l \text{ is } (\texttt{pizza (tastes good)}).

Put in your own words what \textbf{(and \ldots)} does.
We put it in our words:
"(\textbf{and \ldots}) asks questions one at a time
until it finds one whose value is false. Then
\hspace{1cm}(\textbf{and \ldots}) stops with false. If none of the
expressions are false, (\textbf{and \ldots}) is true."

True or false: it is possible that one of the
arguments of \textbf{(and \ldots)} and \textbf{(or \ldots)} is not
considered?\footnote{\texttt{(cond \ldots)} also has the property of not considering all of
its arguments. Because of this property, however, neither
\hspace{1cm}(\textbf{and \ldots}) nor (\textbf{or \ldots}) can be \texttt{defined} as functions in terms
of \texttt{(cond \ldots)}, though both (\textbf{and \ldots}) and (\textbf{or \ldots}) can be
expressed as abbreviations of (\texttt{cond \ldots})-expressions:
\hspace{1cm}(\textbf{and }\alpha \beta) = (\texttt{cond }\alpha \beta \texttt{ (else #f)})
and
\hspace{1cm}(\textbf{or }\alpha \beta) = (\texttt{cond }\alpha \texttt{ #t (else }\beta))
}
True, because (\textbf{and \ldots}) stops if the first
argument has the value \texttt{#f}, and (\textbf{or \ldots})
steps if the first argument has the value \texttt{#t}.

\hspace{1cm}(\texttt{eq\texttt{list}? l1 l2})
where
\hspace{1cm}l1 \text{ is } (\texttt{strawberry ice cream})
and
\hspace{1cm}l2 \text{ is } (\texttt{strawberry ice cream})

\texttt{*Oh My Gawd*: It's Full of Stars}
(eqlist? l1 l2) where
  l1 is (strawberry ice cream)
and
  l2 is (strawberry cream ice)

(eqlist? l1 l2) where
  l1 is (banana ((split)))
and
  l2 is ((banana) (split))

(eqlist? l1 l2) where
  l1 is (beef ((sausage)) (and (soda)))
and
  l2 is (beef ((salami)) (and (soda)))

What is eqlist?

It is a function that determines if two lists are equal.

How many questions will eqlist? have to ask about its arguments?

Nine.

Can you explain why there are nine questions?

Here are our words:
“Each argument may be either
— empty,
— an atom consed onto a list, or
— a list consed onto a list.
For example, at the same time as the first argument may be the empty list, the second argument could be the empty list or have an atom or a list in the car position.”
Write `eqlist?` using `eqan?`:

```
(define eqlist?
  (lambda (l1 l2)
    (cond
      ((and (null? l1) (null? l2)) #t)
      ((and (null? l1) (atom? (car l2))) #f)
      ((null? l1) #f)
      ((and (atom? (car l1)) (null? l2)) #f)
      ((and (atom? (car l1))
          (atom? (car l2)))
       (eqan? (car l1) (car l2))
       (eqlist? (cdr l1) (cdr l2)))
      ((null? l1) #f)
      ((atom? (car l2)) #f)
      (else
       (and (eqlist? (car l1) (car l2))
            (eqlist? (cdr l1) (cdr l2)))))))
```

Is it okay to ask `(atom? (car l2))` in the second question? Yes, because we know that the second list cannot be empty. Otherwise the first question would have been true.

And why is the third question `(null? l1)`? At that point, we know that when the first argument is empty, the second argument is neither the empty list nor a list with an atom as the first element. If `(null? l1)` is true now, the second argument must be a list whose first element is also a list.

True or false: if the first argument is () `eqlist?` responds with #t in only one case. True. For `(eqlist? (quote ()) l2)` to be true, `l2` must also be the empty list.
Does this mean that the questions
\((\text{and} \ (\text{null?} \ l1 \ (\text{null?} \ l2)))\)
and
\((\text{or} \ (\text{null?} \ l1 \ (\text{null?} \ l2)))\)
suffice to determine the answer in the first three cases?

Yes. If the first question is true, \text{eqlist?} responds with \#t; otherwise, the answer is \#f.

**Rewrite eqlist?**

\[
\begin{align*}
\text{eqlist?} & \equiv \\
& (\lambda (l1 \ l2) \\
& \quad (\text{cond} \\
& \quad \quad ((\text{and} \ (\text{null?} \ l1 \ (\text{null?} \ l2))) \ #t) \\
& \quad \quad ((\text{or} \ (\text{null?} \ l1 \ (\text{null?} \ l2))) \ #f) \\
& \quad \quad ((\text{and} \ (\text{atom?} \ (\text{car} \ l1)) \ (\text{atom?} \ (\text{car} \ l2))) \\
& \quad \quad \quad \ (\text{and} \ (\text{eqan?} \ (\text{car} \ l1) \ (\text{car} \ l2)) \ (\text{eqlist?} \ (\text{cdr} \ l1) \ (\text{cdr} \ l2)))) \\
& \quad \quad \quad \ #f) \\
& \quad \quad (\text{else} \\
& \quad \quad \quad \ (\text{and} \ (\text{eqlist?} \ (\text{car} \ l1) \ (\text{car} \ l2)) \ (\text{eqlist?} \ (\text{cdr} \ l1) \ (\text{cdr} \ l2))))))
\end{align*}
\]

**What is an S-expression?**

An S-expression is either an atom or a (possibly empty) list of S-expressions.

**How many questions does equal? ask to determine whether two S-expressions are the same?**

Four. The first argument may be an atom or a list of S-expressions at the same time as the second argument may be an atom or a list of S-expressions.

**Write equal?**

\[
\begin{align*}
\text{equal?} & \equiv \\
& (\lambda (s1 \ s2) \\
& \quad (\text{cond} \\
& \quad \quad ((\text{and} \ (\text{atom?} \ s1 \ (\text{atom?} \ s2))) \ (\text{eqan?} \ s1 \ s2)) \\
& \quad \quad ((\text{atom?} \ s1) \ #f) \\
& \quad \quad ((\text{atom?} \ s2) \ #f) \\
& \quad \quad (\text{else} \ (\text{eqlist?} \ s1 \ s2)))))
\end{align*}
\]
Why is the second question \((\text{atom}\ s1)\)?

If it is true, we know that the first argument is an atom and the second argument is a list.

And why is the third question \((\text{atom}\ s2)\)?

By the time we ask the third question we know that the first argument is not an atom. So all we need to know in order to distinguish between the two remaining cases is whether or not the second argument is an atom. The first argument must be a list.

Can we summarize the second question and the third question as \((\text{or } (\text{atom}\ s1) (\text{atom}\ s2))\)?

Yes, we can!

Simplify \textit{equal}?\n
\[
\text{(define equal?}
\begin{align*}
\text{(lambda } & (s1\ s2) \\
\text{(cond} & \\
& \text{((and } (\text{atom}\ s1) (\text{atom}\ s2)) \\
& \text{(eqan } s1\ s2)) \\
& \text{((or } (\text{atom}\ s1) (\text{atom}\ s2)) \\
& \text{#f)} \\
& \text{(else } (\text{eqlist}\ s1\ s2)))
\end{align*}
\]

Does \textit{equal}? ask enough questions?

Yes. The questions cover all four possible cases.

Now, rewrite \textit{eqlist}? using \textit{equal}?\n
\[
\text{(define eqlist?}
\begin{align*}
\text{(lambda } & (l1\ l2) \\
\text{(cond} & \\
& \text{((and } (\text{null}\ l1) (\text{null}\ l2)) \text{#t)} \\
& \text{((or } (\text{null}\ l1) (\text{null}\ l2)) \text{#f)} \\
& \text{(else} \\
& \text{\hspace{1em} (and } (\text{equal}\ (\text{car}\ l1) (\text{car}\ l2)) \\
& \text{\hspace{1em} \textit{eqlist}\ (\text{cdr}\ l1) (\text{cdr}\ l2)))))
\end{align*}
\]

\*Oh My Gawd*: It’s Full of Stars
Here is \textit{rember} after we replace \textit{lat} by a list \textit{l} of S-expressions and \textit{a} by any S-expression.

\begin{verbatim}
(define rember
    (lambda (s l)
        (cond
            ((null? l) (quote ())
            ((atom? (car l))
                (cond
                    ((equal? (car l) s) (c dr l))
                    (else (cons (car l)
                                (rember s (c dr l))))))))
            (else (cond
                ((equal? (car l) s) (c dr l))
                (else (cons (car l)
                            (rember s
                                    (c dr l))))))))
\end{verbatim}

Can we simplify it?

And how does that differ?

The function \textit{rember} now removes the first matching S-expression \textit{s} in \textit{l}, instead of the first matching atom \textit{a} in \textit{lat}.

Is \textit{rember} a "star" function now?

No.

Why not?

Because \textit{rember} recurs with the \textit{cdr} of \textit{l} only.

Can \textit{rember} be further simplified?

Yes, the inner (\textbf{cond} \ldots) asks questions that the outer (\textbf{cond} \ldots) could ask!
Do it!

Does this new definition look simpler? Yes, it does!

And does it work just as well? Yes, because we knew that all the cases and all the recursions were right before we simplified.

Simplify \textit{insertL*} We can’t. Before we can ask \((eq? (\text{car } l) \text{old})\) we need to know that \((\text{car } l)\) is an atom.

When functions are correct and well-designed, we can think about them easily. And that saved us this time from getting it wrong.

Can all functions that use \(eq\)? and \(=\) be generalized by replacing \(eq\)? and \(=\) by the function \textit{equal}? Not quite; this won’t work for \textit{eqan}? but will work for all others. In fact, disregarding the trivial example of \textit{eqan}? that is exactly what we shall assume.

\begin{verbatim}
(define rember
  (lambda (s l)
    (cond
      ((null? l) (quote ()))
      ((equal? (car l) s) (cdr l))
      (else (cons (car l)
                  (rember s (cdr l)))))))
\end{verbatim}
6.

</tr>
<tr>
<td>True or false: ((\text{numbered? } z)) where (z) is ((2 \times \text{sausage}))</td>
<td>False, because sausage is not a number.</td>
</tr>
<tr>
<td>What is \text{numbered}?</td>
<td>It is a function that determines whether a representation of an arithmetic expression contains only numbers besides the (+, \times,) and (\uparrow).</td>
</tr>
</tbody>
</table>
Now can you write a skeleton for \textit{numbered}? \[
\begin{array}{|l|}
\hline
\textbf{(define numbered?)} \\
\textbf{(lambda (aexp))} \\
\textbf{(cond)} \\
\quad \textbf{_____ _____)} \\
\quad \textbf{_____ _____)} \\
\quad \textbf{_____ _____)} \\
\quad \textbf{_____ _____)} \\
\hline
\end{array}
\]
is a good guess.

What is the first question? \( (atom? \ aexp) \).

What is \( (eq? \ (\text{car} \ (\text{cdr} \ aexp)) \ (\text{quote} \ +)) \)? It is the second question.

Can you guess the third one? \( (eq? \ (\text{car} \ (\text{cdr} \ aexp)) \ (\text{quote} \ \times)) \) is perfect.

And you must know the fourth one. \( (eq? \ (\text{car} \ (\text{cdr} \ aexp)) \ (\text{quote} \ \uparrow)) \), of course.

Should we ask another question about \textit{aexp}? No! So we could replace the previous question by \textbf{else}.

Why do we ask four, instead of two, questions about arithmetic expressions? After all, arithmetic expressions like \((1 + 3)\) are lats.

Because we consider \((1 + 3)\) as a representation of an arithmetic expression in list form, not as a list itself. And, an arithmetic expression is either a number, or two arithmetic expressions combined by \(+\), \times, or \(\uparrow\).
Now you can almost write \textit{numbered}? 

Here is our proposal:

\begin{verbatim}
(define numbered? 
  (lambda (aexp) 
    (cond 
      ((atom? aexp) (number? aexp)) 
      ((eq? (car (cdr aexp)) (quote +)) 
        ... 
      ((eq? (car (cdr aexp)) (quote \times)) 
        ... 
      ((eq? (car (cdr aexp)) (quote \top)) 
        ...))))
\end{verbatim}

Why do we ask \textit{(number? aexp)} when we know that \textit{aexp} is an atom? 

Because we want to know if all arithmetic expressions that are atoms are numbers.

What do we need to know if the \textit{aexp} consists of two arithmetic expressions combined by \textit{+} 

We need to find out whether the two subexpressions are numbered.

In which position is the first subexpression? 

It is the \textit{car} of \textit{aexp}.

In which position is the second subexpression? 

It is the \textit{car} of the \textit{cdr} of the \textit{cdr} of \textit{aexp}.

So what do we need to ask? 

\textbf{(numbered? (car aexp)) and (numbered? (car (cdr (cdr aexp))))}. 

Both must be true.

What is the second answer? 

\textbf{(and (numbered? (car aexp)) (numbered? (car (cdr (cdr aexp)))))}
Try numbered? again.

Since \( aexp \) was already understood to be an arithmetic expression, could we have written \texttt{numbered?} in a simpler way?

\[
\text{(define numbered?}
\begin{array}{l}
\text{(lambda (aexp)}
\text{(cond}
\text{((atom? aexp) (number? aexp))}
\text{((eq? (car (cdr aexp)) (quote +))}
\text{and (numbered? (car aexp))}
\text{(numbered?}
\text{(car (cdr (cdr aexp))))))}
\text{((eq? (car (cdr aexp)) (quote \times))}
\text{and (numbered? (car aexp))}
\text{(numbered?}
\text{(car (cdr (cdr aexp))))))}
\text{((eq? (car (cdr aexp)) (quote \texttt{t}))}
\text{and (numbered? (car aexp))}
\text{(numbered?}
\text{(car (cdr (cdr aexp)))))))))
\end{array})
\text{)}
\]

Yes:

\[
\text{(define numbered?}
\begin{array}{l}
\text{(lambda (aexp)}
\text{(cond}
\text{((atom? aexp) (number? aexp))}
\text{(else}
\text{and (numbered? (car aexp))}
\text{(numbered?}
\text{(car (cdr (cdr aexp)))))))))
\end{array})
\text{)}
\]

Why can we simplify?

Because we know we’ve got the function right.

What is \texttt{(value u)} where \( u \) is 13

\[\text{(value x)} \quad \text{where} \quad x \text{ is } (1 + 3) \]
(value y)
where
y is \(1 + (3 \times 4)\)

(value z)
where \(z\) is cookie

(value nexp) returns what we think is the natural value of a numbered arithmetic expression.

How many questions does value ask about nexp

Four.

Now, let’s attempt to write value

\[
\text{(define value (lambda (nexp)
  (cond ((atom? nexp) \ldots)
        ((eq? (car (cdr nexp)) (quote +)) \ldots)
        ((eq? (car (cdr nexp)) (quote \times)) \ldots)
        (else \ldots))))
\]

What is the natural value of an arithmetic expression that is a number?
It is just that number.

What is the natural value of an arithmetic expression that consists of two arithmetic expressions combined by +
If we had the natural value of the two subexpressions, we could just add up the two values.

Can you think of a way to get the value of the two subexpressions in \((1 + (3 \times 4))\)
Of course, by applying value to 1, and applying value to \((3 \times 4)\).
And in general? By recurring with value on the subexpressions.

---

**The Seventh Commandment**

Recur on the subparts that are of the same nature:
- On the sublists of a list.
- On the subexpressions of an arithmetic expression.

---

Give value another try.

```
(define value
  (lambda (nexp)
    (cond
      ((atom? nexp) nexp)
      ((eq? (car (cdr nexp)) (quote +))
        (+ (value (car nexp))
          (value (car (cdr (cdr nexp))))))
      ((eq? (car (cdr nexp)) (quote ×))
        (∗ (value (car nexp))
          (value (car (cdr (cdr nexp))))))
      (else
        (t (value (car nexp))
          (value
            (car (cdr (cdr nexp)))))))))
```  

Can you think of a different representation of arithmetic expressions? There are several of them.

---

Could (3 4 +) represent 3 + 4 Yes.

Could (+ 3 4) Yes.

Or (plus 3 4) Yes.
Is \((+ (\times 3 6) (\uparrow 8 2))\) a representation of an arithmetic expression?

Try to write the function \textit{value} for a new kind of arithmetic expression that is either:
- a number
- a list of the atom \(+\) followed by two arithmetic expressions,
- a list of the atom \(\times\) followed by two arithmetic expressions, or
- a list of the atom \(\uparrow\) followed by two arithmetic expressions.

You guessed it.

Let’s try an example.

\(\text{(atom? nexp)}\)
where \(nexp\) is \((+ 1 3)\)

\(\text{(eq? (car nexp) (quote +))}\)
where \(nexp\) is \((+ 1 3)\)

And now recur.

What is \(\text{(cdr nexp)}\)
where \(nexp\) is \((+ 1 3)\)

What about

\[
\begin{align*}
\text{(define value} \\
\text{(lambda (nexp)} \\
\quad \text{(cond} \\
\quad \quad \text{(atom? nexp) nexp)} \\
\quad \quad \text{(eq? (car nexp) (quote +))} \\
\quad \quad \quad \quad \text{(value (cdr nexp))}} \\
\quad \quad \text{(eq? (car nexp) (quote \times))} \\
\quad \quad \quad \quad \text{(value (cdr nexp))}} \\
\quad \quad \quad \text{((eq? (car nexp) (quote \times))} \\
\quad \quad \quad \quad \text{(value (cdr nexp))}} \\
\quad \quad \quad \text{(else} \\
\quad \quad \quad \quad \text{(\uparrow (value (cdr nexp))}} \\
\quad \quad \quad \quad \quad \text{(value (cdr (cdr nexp)))))))))
\end{align*}
\]

It’s wrong.

\((+ 1 3)\).

No.

Yes.

Yes.

\((1 3)\).

\textit{Chapter 6}
(1 3) is not our representation of an arithmetic expression.

No, we violated The Seventh Commandment. (1 3) is not a subpart that is a representation of an arithmetic expression! We obviously recurred on a list. But remember, not all lists are representations of arithmetic expressions. We have to recur on subexpressions.

How can we get the first subexpression of a representation of an arithmetic expression?

By taking the car of the cdr.

Is (cdr (cdr nexp)) an arithmetic expression where nexp is (+ 1 3)

No, the cdr of the cdr is (3), and (3) is not an arithmetic expression.

Again, we were thinking of the list (+ 1 3) instead of the representation of an arithmetic expression.

Taking the car of the cdr of the cdr gets us back on the right track.

What do we mean if we say the car of the cdr of nexp

The first subexpression of the representation of an arithmetic expression.

Let’s write a function 1st-sub-exp for arithmetic expressions.

(define 1st-sub-exp
  (lambda (aexp)
    (cond
      (else (car (cdr aexp))))))

Why do we ask else

Because the first question is also the last question.

Can we get by without (cond ...) if we don’t need to ask questions?

Yes, remember one-liners from chapter 4.

(define 1st-sub-exp
  (lambda (aexp)
    (car (cdr aexp))))
Write \texttt{2nd-sub-exp} for arithmetic expressions.

\begin{verbatim}
(define 2nd-sub-exp
  (lambda (aexp)
    (car (cdr (cdr aexp)))))
\end{verbatim}

Finally, let's replace \texttt{(car nexp)} by \texttt{(operator nexp)}

\begin{verbatim}
(define operator
  (lambda (aexp)
    (car aexp)))
\end{verbatim}

Now write \texttt{value} again.

\begin{verbatim}
(define value
  (lambda (nexp)
    (cond
     ((atom? nexp) nexp)
     ((eq? (operator nexp) (quote +))
      (+ (value (1st-sub-exp nexp))
        (value (2nd-sub-exp nexp))))
     ((eq? (operator nexp) (quote \times))
      (\times (value (1st-sub-exp nexp))
        (value (2nd-sub-exp nexp))))
     (else
      (\uparrow (value (1st-sub-exp nexp))
        (value (2nd-sub-exp nexp)))))))
\end{verbatim}

Can we use this \texttt{value} function for the first representation of arithmetic expressions in this chapter? Yes, by changing \texttt{1st-sub-exp} and \texttt{operator}.

Do it!

\begin{verbatim}
(define 1st-sub-exp
  (lambda (aexp)
    (car aexp)))
\end{verbatim}

\begin{verbatim}
(define operator
  (lambda (aexp)
    (car (cdr aexp))))
\end{verbatim}
Wasn’t this easy? Yes, because we used help functions to hide the representation.

The Eighth Commandment
Use help functions to abstract from representations.

Have we seen representations before? Yes, we just did not tell you that they were representations.

For what entities have we used representations? Truth-values! Numbers!

Numbers are representations? Yes. For example 4 stands for the concept four. We chose that symbol because we are accustomed to arabic representations.

What else could we have used? (()) would have served just as well. What about (((())))? How about (1 V)?

Do you remember how many primitives we need for numbers? Four: number?, zero?, add1, and sub1.

Let’s try another representation for numbers. How shall we represent zero now? () is our choice.

How is one represented? (()).

How is two represented? ((())).
Got it? What’s three? Three is ( () () () ).

Write a function to test for zero. 

(define sero? (lambda (n) (null? n)))

Can you write a function that is like \textit{add1}?

(define edd1 (lambda (n) (cons (quote ()) n)))

What about \textit{sub1}?

(define zub1 (lambda (n) (cdr n)))

Is this correct? Let’s see.

What is \((zub1 \ n)\) where \(n\) is ()

— Recall The Law of Cdr. No answer, but that’s fine.

Rewrite \(\oplus\) using this representation.

(define \(\oplus\) (lambda (n m) (cond ((sero? m) n) (else (edd1 (\(\oplus\) n (zub1 m)))))))

Has the definition of \(\oplus\) changed? Yes and no. It changed, but only slightly.
Recall $\text{lat?}$?

Easy:

\[
\text{(define } \text{lat?} \\
(\lambda (l) \\
(\text{cond} \\
((\text{null? } l) \text{ #t}) \\
((\text{atom?} \ (\text{car} \ l)) \ (\text{lat?} \ (\text{cdr} \ l))) \\
(\text{else } \text{#f}))))
\]

But why did you ask?

Do you remember what the value of $(\text{lat? } ls)$ is where $ls$ is $(1 \ 2 \ 3)$?

#t, of course.

What is $(1 \ 2 \ 3)$ with our new numbers?

$((() \ ()()) \ (()()())$.

What is $(\text{lat? } ls)$ where $ls$ is $((() \ ()()) \ (()()())$)

It is very false.

Is that bad?

You must beware of shadows.
7.
Friends and Relations
Is this a set?
(apple peaches apple plum)

No, since apple appears more than once.

True or false: \((\text{set? lat})\)
where
\(\text{lat}\) is (apples peaches pears plums)

\(\#t\), because no atom appears more than once.

How about \((\text{set? lat})\)
where
\(\text{lat}\) is ()

\(\#t\), because no atom appears more than once.

Try to write \(\text{set?}\)

\[
(\text{define set?}\\
(\lambda (\text{lat})\\
 (\text{cond}\\
 (\text{null? lat} \#t)\\
 (\text{else}\\
 (\text{cond}\\
 ((\text{member?} (\text{car lat}) (\text{cdr lat})) \#f)\\
 (\text{else} (\text{set?} (\text{cdr lat}))))))))
)
\]

Simplify \(\text{set?}\)

\[
(\text{define set?}\\
(\lambda (\text{lat})\\
 (\text{cond}\\
 (\text{null? lat} \#t)\\
 ((\text{member?} (\text{car lat}) (\text{cdr lat})) \#f)\\
 (\text{else} (\text{set?} (\text{cdr lat}))))))
)
\]

Does this work for the example
(apple 3 pear 4 9 apple 3 4)

Yes, since \text{member?} is now written using \text{equal?} instead of \text{eq?}.

Were you surprised to see the function \text{member?} appear in the definition of \text{set}?

You should not be, because we have written \text{member?} already, and now we can use it whenever we want.
What is \((\text{makeset lat})\) where 
\(\text{lat}\) is (apple peach pear peach plum apple lemon peach) 
(apple peach pear plum lemon).

Try to write \text{makeset} using \text{member}?  

\[
\text{(define makeset} \newline
\text{(lambda} \ (\text{lat}) \newline
\text{(cond} \newline
\text{((null? lat) (quote ()}) \newline
\text{((member? (car lat) (cdr lat))} \newline
\text{ (makeset (cdr lat)))} \newline
\text{ (else (cons (car lat) \newline
\text{ (makeset (cdr lat)))))))}
\]

Are you surprised to see how short this is? 
We hope so. But don't be afraid: it's right.

Using the previous definition, what is the result of \((\text{makeset lat})\) where 
\(\text{lat}\) is (apple peach pear peach plum apple lemon peach) 
(pear plum apple lemon peach).

Try to write \text{makeset} using \text{multirember}  

\[
\text{(define makeset} \newline
\text{(lambda} \ (\text{lat}) \newline
\text{(cond} \newline
\text{((null? lat) (quote ()}) \newline
\text{ (else (cons (car lat) \newline
\text{ (makeset} \newline\text{ (multirember (car lat) \newline
\text{ (cdr lat))))))))})
\]

What is the result of \((\text{makeset lat})\) using this second definition where 
\(\text{lat}\) is (apple peach pear peach plum apple lemon peach) 
(apple peach pear plum lemon).
Describe in your own words how the second definition of \textit{makeset} works.

Here are our words: 

“The function \textit{makeset} remembers to \textit{cons} the first atom in the list onto the result of the natural recursion, after removing all occurrences of the first atom from the rest of the list.”

Does the second \textit{makeset} work for the example

\begin{verbatim}
(apple 3 pear 4 9 apple 3 4)
\end{verbatim}

Yes, since \textit{multirember} is now written using \textit{equal?} instead of \textit{eq?}.

What is \(\textit{subset? set1 set2}\) where

\(\textit{set1}\) is (5 chicken wings) and

\(\textit{set2}\) is (5 hamburgers 2 pieces fried chicken and light duckling wings)

\#t, because each atom in \textit{set1} is also in \textit{set2}.

What is \(\textit{subset? set1 set2}\) where

\(\textit{set1}\) is (4 pounds of horseradish) and

\(\textit{set2}\) is (four pounds chicken and 5 ounces horseradish)

\#f.

Write \textit{subset?}.

\begin{verbatim}
(define subset?
    (lambda (set1 set2)
        (cond
            ((null? set1) #t)
            (else (cond
                ((member? (car set1) set2)
                (subset? (cdr set1) set2))
                (else #f)))))))
\end{verbatim}
Can you write a shorter version of `subset`?

```
(define subset?
  (lambda (set1 set2)
    (cond
      ((null? set1) #t)
      ((member? (car set1) set2)
       (subset? (cdr set1) set2))
      (else #f)))))
```

Try to write `subset` with `(and ...)`

```
(define subset?
  (lambda (set1 set2)
    (cond
      ((null? set1) #t)
      (else
       (and (member? (car set1) set2)
            (subset? (cdr set1) set2)))))
```

What is `eqset? set1 set2` where

- `set1` is (6 large chickens with wings)
- `set2` is (6 chickens with large wings)

#t.

Write `eqset`?

```
(define eqset?
  (lambda (set1 set2)
    (cond
      ((subset? set1 set2)
       (subset? set2 set1))
      (else #f)))))
```

Can you write `eqset` with only one `cond-line`?

```
(define eqset?
  (lambda (set1 set2)
    (cond
      (else (and (subset? set1 set2)
                 (subset? set2 set1)))))
```
Write the one-liner.

\[
\text{(define \textit{eqset}?}
\begin{align*}
\text{(lambda (set1 set2)} \\
&\text{(and (subset? set1 set2)} \\
&\text{(subset? set2 set1)))}
\end{align*}
\]

What is \((\text{intersect? set1 set2})\) where
\(\text{set1}\) is \((\text{stewed tomatoes and macaroni})\) and
\(\text{set2}\) is \((\text{macaroni and cheese})\)

Define the function \textit{intersect}?.

\[
\text{(define \textit{intersect}?}
\begin{align*}
&\text{(lambda (set1 set2)} \\
&\text{(cond} \\
&\text{((null? set1) #f)} \\
&\text{(else)} \\
&\text{(cond} \\
&\text{((member? (car set1) set2) #t)} \\
&\text{(else (intersect? (cdr set1) set2)))))})
\end{align*}
\]

Write the shorter version.

\[
\text{(define \textit{intersect}?}
\begin{align*}
&\text{(lambda (set1 set2)} \\
&\text{(cond} \\
&\text{((null? set1) #f)} \\
&\text{((member? (car set1) set2) #t)} \\
&\text{(else (intersect? (cdr set1) set2)))))})
\end{align*}
\]

Try writing \textit{intersect}? with \texttt{(or ...)}

\[
\text{(define \textit{intersect}?}
\begin{align*}
&\text{(lambda (set1 set2)} \\
&\text{(cond} \\
&\text{((null? set1) #f)} \\
&\text{(else (or (member? (car set1) set2)} \\
&\text{(intersect? (cdr set1) set2)))))})
\end{align*}
\]

Compare \textit{subset}? and \textit{intersect}?.
What is \((\text{intersect set1 set2})\) (and macaroni).
where  
set1 is (stewed tomatoes and macaroni)
and  
set2 is (macaroni and cheese)

Now you can write the short version of intersect

\[
\begin{align*}
\text{(define intersect} & \text{ (lambda (set1 set2) (cond ((null? set1) (quote ())) ((member? (car set1) set2) (cons (car set1) (intersect (cdr set1) set2))) (else (intersect (cdr set1) set2))))}}
\end{align*}
\]

What is \((\text{union set1 set2})\) (stewed tomatoes casserole macaroni and cheese)
where  
set1 is (stewed tomatoes and macaroni casserole)
and  
set2 is (macaroni and cheese)

Write union

\[
\begin{align*}
\text{(define union} & \text{ (lambda (set1 set2) (cond ((null? set1) set2) ((member? (car set1) set2) (union (cdr set1) set2)) (else (cons (car set1) (union (cdr set1) set2))))))}
\end{align*}
\]
What is this function?

```
(define xxx
  (lambda (set1 set2)
    (cond
      ((null? set1) (quote ()))
      ((member? (car set1) set2)
       (xxx (cdr set1) set2))
      (else (cons (car set1)
                 (xxx (cdr set1) set2))))))
```

In our words:
“It is a function that returns all the atoms in set1 that are not in set2.”
That is, xxx is the (set) difference function.

What is (intersectall l-set) where
l-set is ((a b c) (c a d e) (e f g h a b))

What is (intersectall l-set) where
l-set is ((6 pears and)
  (3 peaches and 6 peppers)
  (8 pears and 6 plums)
  (and 6 prunes with some apples))

Now, using whatever help functions you need, write intersectall assuming that the list of sets is non-empty.

```
(define intersectall
  (lambda (l-set)
    (cond
      ((null? (cdr l-set)) (car l-set))
      (else (intersect (car l-set)
                       (intersectall (cdr l-set)))))))
```

Is this a pair?1
(pear pear)

Yes, because it is a list with only two atoms.

1 A pair in Scheme (or Lisp) is a different but related object.
<table>

<tr>
<td>Did you notice the differences between the last two answers?</td>
<td>No, there aren't any.</td>
</tr>
</tbody>
</table>
They are used to make representations of pairs and to get parts of representations of pairs. See chapter 6.

They will be used to improve readability, as you will soon see.

Redefine first, second, and build as one-liners.

What possible uses do these three functions have?

Can you write third as a one-liner?

Is \( l \) a rel where

\( l \) is (apples peaches pumpkin pie)

No, since \( l \) is not a list of pairs. We use rel to stand for relation.

Is \( l \) a rel where

\( l \) is ((apples peaches)
(pumpkin pie)
(apples peaches))

No, since \( l \) is not a set of pairs.

Is \( l \) a rel where

\( l \) is ((apples peaches) (pumpkin pie))

Yes.

Is \( l \) a rel where

\( l \) is ((4 3) (4 2) (7 6) (6 2) (3 4))

Yes.
Is rel a fun
where
rel is ((4 3) (4 2) (7 6) (6 2) (3 4))

No. We use fun to stand for function.

What is \( (\text{fun? } \text{rel}) \)
where
rel is ((8 3) (4 2) (7 6) (6 2) (3 4))

\#t, because \( (\text{firsts } \text{rel}) \) is a set
—See chapter 3.

What is \( (\text{fun? } \text{rel}) \)
where
rel is ((d 4) (b 0) (b 9) (e 5) (g 4))

\#f, because b is repeated.

Write \text{fun?} with \text{set?} and \text{firsts}

\[
\text{(define fun?}
\\quad (\text{lambda} (\text{rel})
\\quad \quad (\text{set?} (\text{firsts } \text{rel})))))
\]

Is \text{fun?} a simple one-liner?

It sure is.

How do we represent a finite function?

For us, a finite function is a list of pairs in which no first element of any pair is the same as any other first element.

What is \( (\text{revrel rel}) \)
where
rel is ((a 8) (pie pumpkin) (sick got)).

\[
\text{(define revrel}
\\quad (\text{lambda} (\text{rel})
\\quad \quad (\text{cond}
\\quad \quad (\text{null? } \text{rel}) (\text{quote} ()))
\\quad \quad \text{else} (\text{cons} (\text{build}
\\quad \quad \quad (\text{second} (\text{car} \text{rel}))
\\quad \quad \quad (\text{first} (\text{car} \text{rel})))
\\quad \quad \quad (\text{revrel} (\text{cdr} \text{rel})))))))
\]

You can now write \text{revrel}
Would the following also be correct:

\[
\begin{align*}
\text{(define revrel} \\
\quad \text{(lambda (rel) } \\
\quad \quad \text{(cond} \\
\quad \quad \quad \text{((null? rel) (quote ()))} \\
\quad \quad \quad \text{(else (cons (cons } \\
\quad \quad \quad \quad \text{(car (cdr (car rel)))} \\
\quad \quad \quad \quad \text{(cons (car (car rel))} \\
\quad \quad \quad \quad \quad \text{(quote ())))} \\
\quad \quad \quad \text{(revrel (cdr rel))))))))
\end{align*}
\]

Yes, but now do you see how representation aids readability?

Suppose we had the function *revpair* that reversed the two components of a pair like this:

\[
\begin{align*}
\text{(define revpair} \\
\quad \text{(lambda (pair) } \\
\quad \quad \text{(build (second pair) (first pair)))))
\end{align*}
\]

How would you rewrite *revrel* to use this help function?

No problem, and it is even easier to read:

\[
\begin{align*}
\text{(define revrel} \\
\quad \text{(lambda (rel) } \\
\quad \quad \text{(cond} \\
\quad \quad \quad \text{((null? rel) (quote ()))} \\
\quad \quad \quad \text{(else (cons (revpair (car rel))} \\
\quad \quad \quad \quad \text{(revrel (cdr rel))))))))
\end{align*}
\]

Can you guess why *fun* is not a fullfun where

*fun* is \((8 3) (4 2) (7 6) (6 2) (3 4)\)

*fun* is not a fullfun, since the 2 appears more than once as a second item of a pair.

Why is \#t the value of \(\text{(fullfun? fun)}\) where

*fun* is \((8 3) (4 8) (7 6) (6 2) (3 4)\)

Because \((3 8 6 2 4)\) is a set.

What is \(\text{(fullfun? fun)}\) where

*fun* is \((\text{grape raisin})\)

\(\text{(plum prune)}\)

\(\text{(stewed prune)}\)

\#f.
What is \( (\text{fullfun? fun}) \) where \( \text{fun} \) is \((\text{grape raisin}) \)
(\text{plum prune})
(\text{stewed grape}))

\#t, because \((\text{raisin prune grape})\) is a set.

Define \text{fullfun}?

\begin{verbatim}
(define fullfun?
  (lambda (fun)
    (set? (secons fun))))
\end{verbatim}

Can you define \text{seconds}?

It is just like \text{firsts}.

What is another name for \text{fullfun}?

\text{one-to-one}.

Can you think of a second way to write \text{one-to-one}?

\begin{verbatim}
(define one-to-one?
  (lambda (fun)
    (fun? (revers fun))))
\end{verbatim}

Is \((\text{chocolate chip}) \text{ (doughy cookie)})\) a one-to-one function?

Yes, and you deserve one now!

Go and get one!
Or better yet, make your own.

(define cookies
  (lambda ()
    (bake
      (quote (350 degrees))
      (quote (12 minutes))
    )
    (mix
      (quote (walnuts 1 cup))
      (quote (chocolate-chips 16 ounces))
    )
    (mix
      (mix
        (quote (flour 2 cups))
        (quote (oatmeal 2 cups))
        (quote (salt .5 teaspoon))
        (quote (baking-powder 1 teaspoon))
        (quote (baking-soda 1 teaspoon)))
    )
    (mix
      (quote (eggs 2 large))
      (quote (vanilla 1 teaspoon))
    )
    (cream
      (quote (butter 1 cup))
      (quote (sugar 2 cups))))))
8.
Lambda the Ultimate
Remember what we did in `remeber` and `insertL` at the end of chapter 5?

We replaced `eq?` with `equal?`

Can you write a function `remeber-f` that would use either `eq?` or `equal`?

No, because we have not yet told you how.

How can you make `remeber` remove the first a from `(b c a)`

By passing a and `(b c a)` as arguments to `remeber`.

How can you make `remeber` remove the first c from `(b c a)`

By passing c and `(b c a)` as arguments to `remeber`.

How can you make `remeber-f` use `equal` instead of `eq`?

By passing `equal` as an argument to `remeber-f`.

What is `(remeber-f test? a l)`

where

  `test?` is `=`
  a is 5
  and
  l is `(6 2 5 3)`

(6 2 3).

What is `(remeber-f test? a l)`

where

  `test?` is `eq`?
  a is jelly
  and
  l is (jelly beans are good)

(and beans are good).

And what is `(remeber-f test? a l)`

where

  `test?` is `equal`?
  a is (pop corn)
  and
  l is (lemonade (pop corn) and (cake))

(and lemonade and (cake)).

\[1\] L: `(remeber-f (function =) 5 '(6 2 5 3))`, but there is more.
Try to write `rember-f`

```scheme
(define rember-f
  (lambda (test? a l)
    (cond
      ((null? l) (quote ()))
      (else (cond
               ((test? (car l) a)1 (cdr l))
               (else (cons (car l)
                           (rember-f test? a (cdr l)))))))))
```

This is good!

---

1 L: `(funcall test? (car l) a)`. Use `funcall` when invoking a function argument or a function that has not been defined.

What about the short version?

```scheme
(define rember-f
  (lambda (test? a l)
    (cond
      ((null? l) (quote ()))
      ((test? (car l) a) (cdr l))
      (else (cons (car l)
                   (rember-f test? a (cdr l))))))
```

How does `(rember-f test? a l)` act where `test?` is `eq`?

`(rember-f test? a l)` where `test?` is `eq?`, acts like `rember`.

And what about `(rember-f test? a l)` where `test?` is `equal`?

This is just `rember` with `eq?` replaced by `equal?`.

Now we have four functions that do almost the same thing.

Yes:

- `rember` with `=`
- `rember` with `equal?`?
- `rember` with `eq`?

and

`rember-f`.
And *rember-f* can behave like all the others.  Let’s generate all versions with *rember-f*.

<table>

| Using (*define* . . .) give the preceding function a name.               | *define* eq?-c^1
| *(lambda* *(a)*)                                                        | *(lambda* *(a)*)                                                       |
| *(lambda* *(x)*)                                                         | *(lambda* *(x)*)                                                       |
| *(eq?* *x* *a*))                                                         | *(eq?* *x* *a*))                                                       |
| This is our choice.                                                      |                                                                        |
| What is *(eq?-c* *k)* where *k* is salad                                 | Its value is a function that takes *x* as an argument and tests whether it is *eq?* to salad. |

---

**Lambda the Ultimate** 127
So let's give it a name using \(\texttt{(define ...)}\)  
\[
\text{(define eq?-salad (eq?-c k))}
\]
where \(k\) is salad

1 L: (setq eq?-salad (eq?-c 'salad)). Use \texttt{setq} to define a function that can be funcalled.

What is \((eq?-salad y)\)  
where \(y\) is salad

\[\#t.\]

And what is \((eq?-salad y)\)  
where \(y\) is tuna

\[\#f.\]

Do we need to give a name to \(eq?-salad\)  
No, we may just as well ask  
\[
((eq?-c x) y)\]
where  
\(x\) is salad  
and  
\(y\) is tuna.

1 L: (funcall (eq?-c x) y), since \(eq?-salad\) has not been defuned.

Now rewrite \texttt{rember-f} as a function of one argument \texttt{test?} that returns an argument like \texttt{rember} with \texttt{eq?} replaced by \texttt{test?}  
\[
\text{(define rember-f)}
\]
\[
\text{(lambda (test?)
  (lambda (a l)
    (cond
      ((null? l) (quote ()))
      ((test? (car l) a) (cdr l))
      (else (cons (car l) ...))))))}
\]
is a good start.
Describe in your own words the result of
\( \text{(rember-f test?)} \)
where
\( \text{test? is eq?} \)
It is a function that takes two arguments, \( a \) and \( l \). It compares the elements of the list with \( a \), and the first one that is \( eq? \) to \( a \) is removed.

Give a name to the function returned by
\( \text{(rember-f test?)} \)
where
\( \text{test? is eq?} \)
\( \text{(define rember-eq? (rember-f test?))} \)
where
\( \text{test? is eq?} \).

What is \( \text{(rember-eq? a l)} \)
where \( a \) is tuna
and
\( l \) is \( \text{(tuna salad is good)} \)
(\( \text{salad is good} \)).

Did we need to give the name \( \text{rember-eq?} \) to the function \( \text{(rember-f test?)} \)
where
\( \text{test? is eq?} \)
No, we could have written
\( \text{((rember-f test?) a l)} \)
where
\( \text{test? is eq?} \)
\( a \) is \( \text{tuna} \)
and
\( l \) is \( \text{(tuna salad is good)} \).

Now, complete the line
\( \text{(cons (car l) ...)} \)
in \( \text{rember-f} \) so that \( \text{rember-f} \) works.
\( \text{(define rember-f}
\text{(lambda (test?)
(lambda (a l)
(cond
  ((null? l) (quote ()))
  ((test? (car l) a) (cdr l))
  (else (cons (car l)
               ((rember-f test?) a
                (cdr l))))))))

What is \( \text{((rember-f eq?) a l)} \)
where \( a \) is tuna
and
\( l \) is \( \text{(shrimp salad and tuna salad)} \)
(\( \text{shrimp salad and salad} \)).
What is \( (\text{rember-f } \text{eq?}) \ a \ l) \) where \( a \) is \( \text{eq?} \) and \( l \) is \( (\text{equal?} \ \text{eq?} \ \text{eqan?} \ \text{eqlist?} \ \text{eqpair?}) \)\(^1\)

---

\(^1\) Did you notice the difference between \text{eq?} and \text{eq}?
Remember that the former is the atom and the latter is the function.

---

And now transform \text{insertL} to \text{insertL-f} the same way we have transformed \text{rember} into \text{rember-f}

\[
\text{(define insertL-f} \\
\text{\quad (lambda (test?)} \\
\text{\quad \quad (lambda (new old l)} \\
\text{\quad \quad \quad (cond} \\
\text{\quad \quad \quad \quad ((null? l) (quote ()}) \\
\text{\quad \quad \quad \quad ((test? (car l) old) \\
\text{\quad \quad \quad \quad \quad (cons new (cons old (cdr l)))}) \\
\text{\quad \quad \quad \quad (else (cons (car l) \\
\text{\quad \quad \quad \quad \quad ((insertL-f test?) new old \\
\text{\quad \quad \quad \quad \quad (cdr l))))))))})
\text{)}
\]

And, just for the exercise, do it to \text{insertR}

\[
\text{(define insertR-f} \\
\text{\quad (lambda (test?)} \\
\text{\quad \quad (lambda (new old l)} \\
\text{\quad \quad \quad (cond} \\
\text{\quad \quad \quad \quad ((null? l) (quote ()}) \\
\text{\quad \quad \quad \quad ((test? (car l) old) \\
\text{\quad \quad \quad \quad \quad (cons old (cons new (cdr l)))}) \\
\text{\quad \quad \quad \quad (else (cons (car l) \\
\text{\quad \quad \quad \quad \quad ((insertR-f test?) new old \\
\text{\quad \quad \quad \quad \quad (cdr l))))))))})
\text{)}
\]

Are \text{insertR} and \text{insertL} similar? Only the middle piece is a bit different.

Can you write a function \text{insert-g} that would insert either at the left or at the right? If you can, get yourself some coffee cake and relax! Otherwise, don’t give up. You’ll see it in a minute.
Which pieces differ? The second lines differ from each other. In insertL it is:

$$\left( (eq\?\ (\text{car}\ l)\ \text{old})\right.$$  
$$\left. (\text{cons}\ \text{new}\ (\text{cons}\ \text{old}\ (\text{cdr}\ l)))\right),$$

but in insertR it is:

$$\left( (eq\?\ (\text{car}\ l)\ \text{old})\right.$$  
$$\left. (\text{cons}\ \text{old}\ (\text{cons}\ \text{new}\ (\text{cdr}\ l)))\right).$$

Put the difference in words! We say:  
"The two functions cons old and new in a different order onto the cdr of the list l."

So how can we get rid of the difference? You probably guessed it: by passing in a function that expresses the appropriate consing.

Define a function seqL that  
1. takes three arguments, and  
2. conses the first argument onto the result of consing the second argument onto the third argument.

$$\begin{align*}
\text{(define seqL} \\
\quad (\lambda \text{new old l}) \\
\quad (\text{cons new (cons old l)))}) \end{align*}$$

What is: A function that  
1. takes three arguments, and  
2. conses the second argument onto the result of consing the first argument onto the third argument.

$$\begin{align*}
\text{(define seqR} \\
\quad (\lambda \text{new old l}) \\
\quad (\text{cons old (cons new l)))}) \end{align*}$$

Do you know why we wrote these functions? Because they express what the two differing lines in insertL and insertR express.
Try to write the function \textit{insert-g} of one argument \textit{seq} which returns \textit{insertL} where \textit{seq} is \textit{seqL} and which returns \textit{insertR} where \textit{seq} is \textit{seqR}

\begin{verbatim}
(\textbf{define} insert-g
  (\textbf{lambda} (seq)
    (\textbf{lambda} (new old l)
      (\textbf{cond}
        ((null? l) (quote ()))
        ((eq? (\textbf{car} l) old) (\textbf{seq} new old (\textbf{cdr} l)))
        (else (\textbf{cons} (\textbf{car} l)
          ((insert-g seq) new old (\textbf{cdr} l))))))))

(define insertL (insert-g seqL))
(define insertR (insert-g seqR))
\end{verbatim}

Now define \textit{insertL} with \textit{insert-g}

\begin{verbatim}
(define insertL (insert-g seqL))
\end{verbatim}

And \textit{insertR}.

\begin{verbatim}
(define insertR (insert-g seqR))
\end{verbatim}

Is there something unusual about these two definitions?

Yes. Earlier we would probably have written

\begin{verbatim}
 (define insertL (insert-g seq))
\end{verbatim}

where \textit{seq} is \textit{seqL}

and

\begin{verbatim}
 (define insertR (insert-g seq))
\end{verbatim}

where \textit{seq} is \textit{seqR}.

But, using “where” is unnecessary when you pass functions as arguments.

Is it necessary to give names to \textit{seqL} and \textit{seqR}

Not really. We could have passed their definitions instead.

Define \textit{insertL} again with \textit{insert-g} Do not pass in \textit{seqL} this time.

\begin{verbatim}
(define insertL
  (insert-g
    (\textbf{lambda} (new old l)
      (\textbf{cons} new (\textbf{cons} old l)))))
\end{verbatim}
Is this better? Yes, because you do not need to remember as many names. You can

\[(\text{rember~func-name~"your-mind"})\]
where func-name is seqL.

Do you remember the definition of subst

Here is one.

\[
\begin{align*}
\text{(define subst} & \text{~(lambda} (\text{new old l}) \\
& (\text{cond} \\
& ((\text{null?~l})~(\text{quote~}())) \\
& ((\text{eq?~(car~l)~old}) \\
& (~\text{(cons~new~(cdr~l)}))) \\
& (\text{else~(cons~car~l)} \\
& (~\text{(subst~new~old~(cdr~l)}))))))
\end{align*}
\]

Does this look familiar? Yes, it looks like insertL or insertR. Just the answer of the second cond-line is different.

Define a function like seqL or seqR for subst

What do you think about this?

\[
\begin{align*}
\text{(define seqS} & \text{~(lambda} (\text{new old l}) \\
& (~\text{(cons~new~l)}))
\end{align*}
\]

And now define subst using insert-g

\[
\text{(define subst~(insert-g seqS))}
\]

And what do you think yyy is

\[
\begin{align*}
\text{(define yyy} & \text{~(lambda} (a~l) \\
& (~\text{(insert-g~seqrem) #f~a~l}))
\end{align*}
\]

where

\[
\begin{align*}
\text{(define seqrem} & \text{~(lambda} (\text{new old l}) \\
& ~l))
\end{align*}
\]

Surprise! It is our old friend rember

\[
\begin{align*}
\text{Hint: Step through the evaluation of} & \text{~(yyy~a~l)} \\
& \text{where} \\
& a \text{ is sausage} \\
& \text{and} \\
& l \text{ is (pizza with sausage and bacon).}
\end{align*}
\]

What role does #f play?
What you have just seen is the power of abstraction.

The Ninth Commandment
Abstract common patterns with a new function.

Have we seen similar functions before?
Yes, we have even seen functions with similar lines.

Do you remember value from chapter 6?

```scheme
(define value
  (lambda (nexp)
    (cond
      ((atom? nexp) nexp)
      ((eq? (operator nexp) (quote +))
        (+ (value (1st-sub-exp nexp))
            (value (2nd-sub-exp nexp))))
      ((eq? (operator nexp) (quote ×))
        (× (value (1st-sub-exp nexp))
            (value (2nd-sub-exp nexp))))
      (else
        (↑ (value (1st-sub-exp nexp))
            (value (2nd-sub-exp nexp)))))))
```

Do you see the similarities?
The last three answers are the same except for the +, ×, and ↑.

Can you write the function atom-to-function which:
1. Takes one argument x and
2. returns the function + if (eq? x (quote +))
   returns the function × if (eq? x (quote ×)) and
   returns the function ↑ otherwise?

```scheme
(define atom-to-function
  (lambda (x)
    (cond
      ((eq? x (quote +)) +)
      ((eq? x (quote ×)) ×)
      (else ↑))))
```
What is \((\text{atom-to-function}\ (\text{operator}\ \text{nexp}))\) where 
\(\text{nexp}\) is \((+\ 5\ 3)\) 

The function \(\oplus\), not the atom \(\pm\).

Can you use \text{atom-to-function} to rewrite \text{value} with only two \text{cond}-lines? 

Of course.

\[
\begin{align*}
\text{(define } \text{value} & \text{ (lambda } (\text{nexp}) \\
& \text{(cond} \\
& \quad ((\text{atom}\ ?\ \text{nexp}) \ \text{nexp}) \\
& \quad \text{(else}} \\
& \quad \quad ((\text{atom-to-function} \\
& \quad \quad \quad \text{(operator}\ \text{nexp})) \\
& \quad \quad \quad ((\text{value}\ \text{(1st-sub-exp}\ \text{nexp})) \\
& \quad \quad \quad \text{(value}\ \text{(2nd-sub-exp}\ \text{nexp))))))))
\end{align*}
\]

Is this quite a bit shorter than the first version? 

Yes, but that’s okay. We haven’t changed its meaning.

Time for an apple? 

One a day keeps the doctor away.

Here is \text{multirember} again.

\[
\begin{align*}
\text{(define } \text{multirember} & \text{ (lambda } (a\ \text{lat}) \\
& \text{(cond} \\
& \quad ((\text{null}\ ?\ \text{lat}) \ \text{(quote})))) \\
& \quad \quad ((\text{eq}\ ?\ \text{(car}\ \text{lat})\ \text{a}) \\
& \quad \quad \quad \text{(multirember}\ a\ \text{(cdr}\ \text{lat}))) \\
& \quad \quad \text{(else} \\
& \quad \quad \quad \text{(cons}\ \text{(car}\ \text{lat}) \\
& \quad \quad \quad \quad \text{(multirember}\ a \\
& \quad \quad \quad \quad \quad \quad \text{(cdr}\ \text{lat})))))
\end{align*}
\]

No problem.

Write \text{multirember-f}

\[
\begin{align*}
\text{(define } \text{multirember-f} & \text{ (lambda } (\text{test}\ ?) \\
& \text{(lambda } (a\ \text{lat}) \\
& \text{(cond} \\
& \quad ((\text{null}\ ?\ \text{lat}) \ \text{(quote})))) \\
& \quad \quad ((\text{test}\ ?\ \text{(car}\ \text{lat})\ \text{a}) \\
& \quad \quad \quad \text{(multirember-f}\ \text{test}\ ?\ \text{a} \\
& \quad \quad \quad \quad \text{(cdr}\ \text{lat}))) \\
& \quad \quad \text{(else} \\
& \quad \quad \quad \text{(cons}\ \text{(car}\ \text{lat}) \\
& \quad \quad \quad \quad \text{(multirember-f}\ \text{test}\ ?\ \text{a} \\
& \quad \quad \quad \quad \quad \quad \text{(cdr}\ \text{lat})))))
\end{align*}
\]

What is \((\text{(multirember-f}\ \text{test}\ ?)\ a\ \text{lat})\) where 
\text{test}\ ?\ is \text{eq}? 
\text{a} is \text{tuna} 
and 
\text{lat} is \text{(shrimp salad salad and tuna)}

(shrimp salad salad and).
Wasn’t that easy? Yes.

Define `multirember-eq?` using `multirember-f`

```
(define multirember-eq?
  (multirember-f test?))
```

where `test?` is `eq?`.

Do we really need to tell `multirember-f` about `tuna` As `multirember-f` visits all the elements in `lat`, it always looks for `tuna`.

Does `test?` change as `multirember-f` goes through `lat` No, `test?` always stands for `eq?`, just as `a` always stands for `tuna`.

Can we combine `a` and `test?` Well, `test?` could be a function of just one argument and could compare that argument to `tuna`.

How would it do that? The new `test?` takes one argument and compares it to `tuna`.

Here is one way to write this function.

```
(define eq?-tuna
  (eq?-c k))
```

where `k` is `tuna` Can you think of a different way of writing this function?

Yes, and here is a different way:

```
(define eq?-tuna
  (eq?-c (quote tuna)))
```

Have you ever seen definitions that contain atoms? Yes, 0, `(quote ×)`, `(quote +)`, and many more.

Chapter 8
Perhaps we should now write \texttt{multiremberT} which is similar to \texttt{multirember-f}.

Instead of taking \texttt{test?} and returning a function, \texttt{multiremberT} takes a function like \texttt{eq?-tuna} and a lat and then does its work.

This is not really difficult.

\begin{verbatim}
(define multiremberT
  (lambda (test? lat)
    (cond
      ((null? lat) (quote ()))
      ((test? (car lat))
        (multiremberT test? (cdr lat)))
      (else (cons (car lat)
                    (multiremberT test? (cdr lat)))))))
\end{verbatim}

What is \texttt{(multiremberT test? lat)}

where

\texttt{test?} is \texttt{eq?-tuna}

and

\texttt{lat} is \texttt{(shrimp salad tuna salad and)}

(shrimp salad salad and).

Is this easy?  It's not bad.

How about this?

\begin{verbatim}
(define multirember&co
  (lambda (a lat col)
    (cond
      ((null? lat)
        (col (quote ()) (quote ()))))
      ((eq? (car lat) a)
        (multirember&co a (cdr lat))
        (lambda (newlat seen)
          (col newlat
            (cons (car lat) seen)))))
      (else
        (multirember&co a (cdr lat)
        (lambda (newlat seen)
          (col (cons (car lat) newlat)
            seen)))))
\end{verbatim}

Now that looks really complicated!
Here is something simpler:

```
(define a-friend
  (lambda (x y)
    (null? y)))
```

What is the value of

```
(multirember&co a lat col)
```

where
- `a` is tuna
- `lat` is (strawberries tuna and swordfish)
and
- `col` is `a-friend`

So let's try a friendlier example. What is the value of

```
(multirember&co a lat col)
```

where
- `a` is tuna
- `lat` is ()
and
- `col` is `a-friend`

And what is

```
(multirember&co a lat col)
```

where
- `a` is tuna
- `lat` is (tuna)
and
- `col` is `a-friend`

What are the other arguments that `multirember&co` uses for the natural recursion?

The first one is clearly tuna. The third argument is a new function.

What is the name of the third argument?

`col`.

Do you know what `col` stands for?

The name `col` is short for “collector.”
A collector is sometimes called a “continuation.”
Here is the new collector:

```
(define new-friend
  (lambda (newlat seen)
    (col newlat
      (cons (car lat) seen)))
)
```

where

(car lat) is tuna
and
col is a-friend
Can you write this definition differently?

Can we also replace col with a-friend in such definitions because col is to a-friend what (car lat) is to tuna

Yes, we can:

```
(define new-friend
  (lambda (newlat seen)
    (a-friend newlat
      (cons (quote tuna) seen)))
)
```

And now?

multirember&co finds out that (null? lat) is true, which means that it uses the collector on two empty lists.

Which collector is this?

new-friend

How does a-friend differ from new-friend

new-friend uses a-friend on the empty list and the value of

(cons (quote tuna) (quote ())).

And what does the old collector do with such arguments?

It answers #f, because its second argument is (tuna), which is not the empty list.

What is the value of

(multirember&co a lat a-friend)

where a is tuna
and
lat is (and tuna)

This time around multirember&co recurs with yet another friend.

```
(define latest-friend
  (lambda (newlat seen)
    (a-friend (cons (quote and) newlat)
      seen)))
```
And what is the value of this recursive use of \texttt{multirember&co} \#f, since \((a\text{-friend}\ \text{ls1}\ \text{ls2})\)
where
\text{ls1} is (and)
and\text{ls2} is (tuna)
is \#f.

What does \((\text{multirember&co}\ a\ \text{lat} \ f)\) do? It looks at every atom of the \text{lat} to see
whether it is \text{eq?} to \text{a}. Those atoms that are
not are collected in one list \text{ls1}; the others
for which the answer is true are collected in a
second list \text{ls2}. Finally, it determines the
value of \((f\ \text{ls1}\ \text{ls2})\).

Final question: What is the value of
\((\text{multirember&co} \ (\text{quote} \ \text{tuna})\ \text{ls} \ \text{col})\)
where
\text{ls} is (strawberries tuna and swordfish)
and
\text{col} is
\begin{verbatim}
(define last-friend
  (lambda (x y)
    (length x)))
\end{verbatim}

3, because \text{ls} contains three things that are
not tuna, and therefore \text{last-friend} is used on
(strawberries and swordfish) and (tuna).

Yes! It's a strange meal, but we have seen foreign
foods before.

The Tenth Commandment

Build functions to collect more than one value at a time.
Here is an old friend.

\[
(\text{define } \text{multiinsertL} \\
(\text{lambda} (\text{new} \ \text{old} \ \text{lat}) \\
(\text{cond} \\
\quad ((\text{null?} \ \text{lat}) \ (\text{quote} ())) \\
\quad ((\text{eq?} \ (\text{car} \ \text{lat}) \ \text{old}) \\
\quad \quad (\text{cons} \ \text{new} \\
\quad \quad \quad (\text{cons} \ \text{old} \\
\quad \quad \quad \quad (\text{multiinsertL} \ \text{new} \ \text{old} \\
\quad \quad \quad \quad \ (\text{cdr} \ \text{lat}))))) \\
\quad \text{else} (\text{cons} \ (\text{car} \ \text{lat}) \\
\quad \quad (\text{multiinsertL} \ \text{new} \ \text{old} \\
\quad \quad \ (\text{cdr} \ \text{lat}))))))
\]

Do you also remember \text{multiinsertR}

\[
(\text{define } \text{multiinsertR} \\
(\text{lambda} (\text{new} \ \text{old} \ \text{lat}) \\
(\text{cond} \\
\quad ((\text{null?} \ \text{lat}) \ (\text{quote} ())) \\
\quad ((\text{eq?} \ (\text{car} \ \text{lat}) \ \text{old}) \\
\quad \quad (\text{cons} \ \text{old} \\
\quad \quad \quad (\text{cons} \ \text{new} \\
\quad \quad \quad \quad (\text{multiinsertR} \ \text{new} \ \text{old} \\
\quad \quad \quad \quad \ (\text{cdr} \ \text{lat}))))) \\
\quad \text{else} (\text{cons} \ (\text{car} \ \text{lat}) \\
\quad \quad (\text{multiinsertR} \ \text{new} \ \text{old} \\
\quad \quad \ (\text{cdr} \ \text{lat}))))))
\]

Now try \text{multiinsertLR}

Hint: \text{multiinsertLR} inserts \text{new} to the left of \text{oldL} and to the right of \text{oldR} in \text{lat} if \text{oldL} are \text{oldR} are different.

\[
(\text{define } \text{multiinsertLR} \\
(\text{lambda} (\text{new} \ \text{oldL} \ \text{oldR} \ \text{lat}) \\
(\text{cond} \\
\quad ((\text{null?} \ \text{lat}) \ (\text{quote} ())) \\
\quad ((\text{eq?} \ (\text{car} \ \text{lat}) \ \text{oldL}) \\
\quad \quad (\text{cons} \ \text{new} \\
\quad \quad \quad (\text{cons} \ \text{oldL} \\
\quad \quad \quad \quad (\text{multiinsertLR} \ \text{new} \ \text{oldL} \ \text{oldR} \\
\quad \quad \quad \quad \ (\text{cdr} \ \text{lat})))))) \\
\quad ((\text{eq?} \ (\text{car} \ \text{lat}) \ \text{oldR}) \\
\quad \quad (\text{cons} \ \text{oldR} \\
\quad \quad \quad (\text{cons} \ \text{new} \\
\quad \quad \quad \quad (\text{multiinsertLR} \ \text{new} \ \text{oldL} \ \text{oldR} \\
\quad \quad \quad \quad \ (\text{cdr} \ \text{lat})))))) \\
\quad \text{else} (\text{cons} \ (\text{car} \ \text{lat}) \\
\quad \quad (\text{multiinsertLR} \ \text{new} \ \text{oldL} \ \text{oldR} \\
\quad \quad \ (\text{cdr} \ \text{lat}))))))
\]

This is a way of combining the two functions.

The function \text{multiinsertLR\&co} is to \text{multiinsertLR} what \text{multirember\&co} is to \text{multirember}

Does this mean that \text{multiinsertLR\&co} takes one more argument than \text{multiinsertLR}?

Yes, and what kind of argument is it?

It is a collector function.
When `multiinsertLR&co` is done, it will use `col` on the new lat, on the number of left insertions, and the number of right insertions. Can you write an outline of `multiinsertLR&co`?

Sure, it is just like `multiinsertLR`.

```scheme
(define multiinsertLR&co
  (lambda (new oldL oldR lat col)
    (cond
      ((null? lat)
       (col (quote ()) 0 0))
      ((eq? (car lat) oldL)
       (multiinsertLR&co new oldL oldR (cdr lat)
        (lambda (newlat L R)
          ...)))
      ((eq? (car lat) oldR)
       (multiinsertLR&co new oldL oldR (cdr lat)
        (lambda (newlat L R)
          ...)))
      (else
       (multiinsertLR&co new oldL oldR (cdr lat)
        (lambda (newlat L R)
          ...))])))
```

Why is `col` used on `(quote ())` 0 and 0 when `(null? lat)` is true?

The empty `lat` contains neither `oldL` nor `oldR`. And this means that 0 occurrences of `oldL` and 0 occurrences of `oldR` are found and that `multiinsertLR` will return `()` when `lat` is empty.

So what is the value of

```
(multiinsertLR&co
  (quote cranberries)
  (quote fish)
  (quote chips)
  (quote ())
  col)
```

It is the value of `(col (quote ()) 0 0)`, which we cannot determine because we don't know what `col` is.

Is it true that `multiinsertLR&co` will use the new collector on three arguments when `(car lat)` is equal to neither `oldL` nor `oldR`?

Yes, the first is the lat that `multiinsertLR` would have produced for `(cdr lat)`, `oldL`, and `oldR`. The second and third are the number of insertions that occurred to the left and right of `oldL` and `oldR`, respectively.
Is it true that \texttt{multiinsertLR&co} then uses the function \texttt{col} on \texttt{(cons (car lat) newlat)} because it copies the list unless an \texttt{oldL} or an \texttt{oldR} appears?

Yes, it is true, so we know what the new collector for the last case is:

\[
\text{(lambda} (\text{newlat L R})
\quad \text{(col} \ (\text{cons} \ (\text{car} \ \text{lat}) \ \text{newlat}) \ \text{L} \ \text{R})).
\]

Why are \texttt{col}'s second and third arguments just \texttt{L} and \texttt{R}?

If \texttt{(car lat)} is neither \texttt{oldL} nor \texttt{oldR}, we do not need to insert any new elements. So, \texttt{L} and \texttt{R} are the correct results for both \texttt{(cdr lat)} and all of \texttt{lat}.

Here is what we have so far. And we have even thrown in an extra collector:

\[
\begin{align*}
\text{(define} \ \text{multiinsertLR&co} \\
& \quad \text{(lambda} (\text{new oldL oldR lat col}) \\
& \quad \quad \text{(cond} \\
& \quad \quad \quad \text{(null} ? \ \text{lat}) \\
& \quad \quad \quad \quad \text{(col} \ \text{(quote} () \text{) 0 0})) \\
& \quad \quad \quad \text{(eq?} \ (\text{car} \ \text{lat}) \ \text{oldL}) \\
& \quad \quad \quad \quad \text{(multiinsertLR&co} \ \text{new oldL oldR} \\
& \quad \quad \quad \quad \quad \text{(cdr lat}) \\
& \quad \quad \quad \quad \quad \text{(lambda} \ \text{newlat L R}) \\
& \quad \quad \quad \quad \quad \quad \text{(col} \ \text{(cons new} \\
& \quad \quad \quad \quad \quad \quad \quad \text{(cons oldL newlat)}) \\
& \quad \quad \quad \quad \quad \quad \quad \quad \text{(add1 L) R))) \\
& \quad \quad \quad \text{(eq?} \ (\text{car} \ \text{lat}) \ \text{oldR}) \\
& \quad \quad \quad \quad \text{(multiinsertLR&co} \ \text{new oldL oldR} \\
& \quad \quad \quad \quad \quad \text{(cdr lat}) \\
& \quad \quad \quad \quad \quad \text{(lambda} \ \text{newlat L R}) \\
& \quad \quad \quad \quad \quad \quad \text{(...)))} \\
& \quad \quad \text{else} \\
& \quad \quad \quad \text{(multiinsertLR&co} \ \text{new oldL oldR} \\
& \quad \quad \quad \quad \quad \text{(cdr lat}) \\
& \quad \quad \quad \quad \quad \text{(lambda} \ \text{newlat L R}) \\
& \quad \quad \quad \quad \quad \quad \text{(col} \ \text{(cons (car lat) newlat} \\
& \quad \quad \quad \quad \quad \quad \quad \quad \text{L R)))))))))) \\
\end{align*}
\]

Can you fill in the dots?

The incomplete collector is similar to the extra collector. Instead of adding one to \texttt{L}, it adds one to \texttt{R}, and instead of \texttt{consing new} onto \texttt{consing oldL onto newlat}, it \texttt{conses oldR} onto the result of \texttt{consing new} onto \texttt{newlat}.

So can you fill in the dots?

Yes, the final collector is

\[
\text{(lambda} (\text{newlat L R}) \\
\quad \text{(col} \ \text{(cons oldR} \ \text{(cons new newlat}) \\
\quad \quad \text{L} \ \text{(add1 R)}))).
\]
What is the value of 
\[(\text{multiinsertLR} \& \text{co new oldL oldR lat col})\]
where
- new is salty
- oldL is fish
- oldR is chips
and
- lat is (chips and fish or fish and chips)

It is the value of \((\text{col newlat} \ 2 \ 2)\)
where
- newlat is (chips salty and salty fish
  or salty fish and chips salty).

Is this healthy?       Looks like lots of salt. Perhaps dessert is sweeter.

Do you remember what *-functions are?  Yes, all *-functions work on lists that are either

- empty,
- an atom consed onto a list, or
- a list consed onto a list.

Now write the function \(\text{evens-only*}\) which removes all odd numbers from a list of nested lists. Here is \(\text{even}\)?

\[
\begin{align*}
\text{(define even?} \\
\text{ (lambda} \ (n) \\
\quad (\ast \ (\div \ n \ 2) \ 2) \ n))))
\end{align*}
\]

Now that we have practiced this way of writing functions, \(\text{evens-only*}\) is just an exercise:

\[
\begin{align*}
\text{(define evens-only*} \\
\text{ (lambda} \ (l) \\
\quad (\text{cond} \\
\quad \quad \ ((\text{null?} \ l) \ (\text{quote} \ ())) \\
\quad \quad \ ((\text{atom?} \ \text{(car} \ l)) \\
\quad \quad \quad \quad \ (\text{cond} \\
\quad \quad \quad \quad \quad \ (\text{even?} \ \text{(car} \ l)) \\
\quad \quad \quad \quad \quad \quad \ (\text{cons} \ \text{(car} \ l) \\
\quad \quad \quad \quad \quad \quad \quad \quad \ (\text{evens-only*} \ \text{(cdr} \ l)))))) \\
\quad \quad \quad \quad \quad \ (\text{else} \ (\text{evens-only*} \ \text{(cdr} \ l)))))) \\
\quad \quad \ (\text{else} \ (\text{cons} \ (\text{evens-only*} \ \text{(car} \ l)) \\
\quad \quad \quad \quad \ (\text{evens-only*} \ \text{(cdr} \ l))))))))
\end{align*}
\]

What is the value of \((\text{evens-only*} \ l)\)
where
\(l\) is \(((\ 9 \ 1 \ 2 \ 8) \ 3 \ 10 \ ((9 \ 9) \ 7 \ 6) \ 2)\)

\(((2 \ 8) \ 10 \ ((\ 6) \ 2)\).

Chapter 8
What is the sum of the odd numbers in \( l \)
where
\[ l = ((9 \ 1 \ 2 \ 8) \ 3 \ 10 \ ((9 \ 9) \ 7 \ 6) \ 2) \]
\[ 9 + 1 + 3 + 9 + 9 + 7 = 38. \]

What is the product of the even numbers in \( l \)
where
\[ l = ((9 \ 1 \ 2 \ 8) \ 3 \ 10 \ ((9 \ 9) \ 7 \ 6) \ 2) \]
\[ 2 \times 8 \times 10 \times 6 \times 2 = 1920. \]

Can you write the function \textit{evens-only*co}?
It builds a nested list of even numbers by removing the odd ones from its argument and simultaneously multiplies the even numbers and sums up the odd numbers that occur in its argument.

This is full of stars!

Here is an outline. Can you explain what \((\textit{evens-only*co} \ (\textit{car} \ l) \ldots)\) accomplishes?

It visits every number in the \textit{car} of \( l \) and collects the list without odd numbers, the product of the even numbers, and the sum of the odd numbers.

It uses the collector, which we haven’t defined yet.

\begin{verbatim}
(define evens-only*\textit{co}
(l lambda (l col)
  (cond
    ((null? l)
     (col (quote ()) 1 0))
    ((atom? (car l))
     (cond
      ((even? (car l))
       (evens-only*\textit{co} (cdr l)
        (lambda (newl p s)
          (col (cons (car l) newl)
               (\times (car l) p) s)))))
      (else (evens-only*\textit{co} (cdr l)
        (lambda (newl p s)
          (col newl
           p (+ (car l) s))))))
      (else (evens-only*\textit{co} (car l)
        \ldots)))))
\end{verbatim}
And what does the collector do?

It uses `evens-only*&co` to visit the `cdr` of `l` and to collect the list that is like `(cdr l)`, without the odd numbers of course, as well as the product of the even numbers and the sum of the odd numbers.

Does this mean the unknown collector looks roughly like this:

```
(lambdacal ap as)
      (evens-only*&co (cdr l)
          ...
))
```

Yes.

And when `(evens-only*&co (cdr l) ...)` is done with its job, what happens then?

The yet-to-be-determined collector is used, just as before.

What does the collector for `(evens-only*&co (cdr l) ...)` do?

It `conses` together the results for the lists in the `car` and the `cdr` and multiplies and adds the respective products and sums. Then it passes these values to the old collector:

```
(lambdacal ap as)
      (evens-only*&co (cdr l)
          (lambdacdl dp ds)
              (col (cons al dl)
                 (× ap dp)
                 (+ as ds)))))
```

Perfect.

Does this all make sense now?

(38 1920 (2 8) 10 ((6) 2)).

What is the value of `(evens-only*&co l the-last-friend)`

(38 1920 (2 8) 10 ((6) 2)).

where

l is `((9 1 2 8) 3 10 ((9 9) 7 6) 2)` and

the-last-friend is defined as follows:

```
(define the-last-friend
    (lambdacnewl product sum)
        (cons sum
            (cons product
                newl))))
```
Whew! Is your brain twisted up now? Go eat a pretzel; don’t forget the mustard.
9.

...and Again, and Again, and Again,...
Are you in the mood for caviar

Then we must go looking for it.

What is \((\text{looking a lat})\)
where \(a\) is caviar
and
\(\text{lat}\) is \((6 2 4 \text{ caviar} 5 7 3)\)

#t,
caviar is obviously in \textit{lat}.

\((\text{looking a lat})\)
where \(a\) is caviar
and
\(\text{lat}\) is \((6 2 \text{ grits caviar} 5 7 3)\)

#f.

Were you expecting something different?

Yes, caviar is still in \textit{lat}.

True enough, but what is the first number in the \textit{lat}?

6.

And what is the sixth element of \textit{lat}

7.

And what is the seventh element?

3.

So looking clearly can’t find caviar

True enough,
because the third element is grits, which does not even resemble caviar.

Here is looking

\begin{verbatim}
(define looking
  (lambda (a lat)
    (keep-looking a (pick 1 lat) lat)))
\end{verbatim}

We did not expect you to know this.

Write \textit{keep-looking}

\((\text{looking a lat})\)
where \(a\) is caviar
and
\(\text{lat}\) is \((6 2 4 \text{ caviar} 5 7 3)\)

#t,
because \((\text{keep-looking a} \ 6 \ \text{lat})\) has the same answer as \((\text{keep-looking a} \ (\text{pick} \ 1 \ \text{lat}) \ \text{lat})\).

... and Again, and Again, and Again, ...
What is \((\textit{pick} \ 6 \ \textit{lat})\) where \(\textit{lat} \) is \((6 \ 2 \ 4 \ \text{caviar} \ 5 \ 7 \ 3)\)?

So what do we do? \((\textit{keep-looking} \ a \ 7 \ \textit{lat})\) where \(a\) is caviar and \(\textit{lat} \) is \((6 \ 2 \ 4 \ \text{caviar} \ 5 \ 7 \ 3)\).

What is \((\textit{pick} \ 7 \ \textit{lat})\) where \(\textit{lat} \) is \((6 \ 2 \ 4 \ \text{caviar} \ 5 \ 7 \ 3)\)?

So what is \((\textit{keep-looking} \ a \ 3 \ \textit{lat})\) where \(a\) is caviar and \(\textit{lat} \) is \((6 \ 2 \ 4 \ \text{caviar} \ 5 \ 7 \ 3)\)?

Which is? \(#t\).

Write \textit{keep-looking}.

\[
(\text{define} \ \textit{keep-looking} \\
(\lambda (a \ \textit{sorn} \ \textit{lat}) \\
(\text{cond} \\
((\text{number?} \ \textit{sorn}) \\
(\textit{keep-looking} \ a \ (\textit{pick} \ \textit{sorn} \ \textit{lat}) \ \textit{lat})) \\
(\text{else} \ (\text{eq?} \ \textit{sorn} \ a)))))
\]

Can you guess what \(\textit{sorn}\) stands for? Symbol or number.

What is unusual about \textit{keep-looking}? It does not recur on a part of \(\textit{lat}\).

We call this “unnatural” recursion. It is truly unnatural.
<table>
<thead>
<tr>
<th>Question</th>
<th>Answer</th>
</tr>
</thead>
<tbody>
<tr>
<td>Does <em>keep-looking</em> appear to get closer to its goal?</td>
<td>Yes, from all available evidence.</td>
</tr>
<tr>
<td>Does it always get closer to its goal?</td>
<td>Sometimes the list may contain neither caviar nor grits.</td>
</tr>
<tr>
<td>That is correct. A list may be a tup.</td>
<td>Yes, if we start <em>looking</em> in (7 2 4 7 5 6 3), we will never stop looking.</td>
</tr>
<tr>
<td>What is ( (\text{looking a lat}) ) where ( a ) is caviar and ( \text{lat} ) is (7 1 2 caviar 5 6 3))</td>
<td>This is strange!</td>
</tr>
<tr>
<td>Yes, it is strange. What happens?</td>
<td>We keep looking and looking and looking …</td>
</tr>
<tr>
<td>Functions like <em>looking</em> are called partial functions. What do you think the functions we have seen so far are called?</td>
<td>They are called total.</td>
</tr>
<tr>
<td>Can you define a shorter function that does not reach its goal for some of its arguments?</td>
<td>( \text{(define eternity} ) ) (lambda ( (x) ) ( \text{(eternity x)} )))</td>
</tr>
<tr>
<td>For how many of its arguments does <em>eternity</em> reach its goal?</td>
<td>None, and this is the most unnatural recursion possible.</td>
</tr>
<tr>
<td>Is <em>eternity</em> partial?</td>
<td>It is the most partial function.</td>
</tr>
<tr>
<td>What is ( (\text{shift} \ x) ) where ( x ) is ( ((a \ b) \ c) ))</td>
<td>( (a \ (b \ c)) ).</td>
</tr>
</tbody>
</table>

... and Again, and Again, and Again, …
What is \((\text{shift } x)\) where 
\(x = ((a\ b)\ (c\ d))\)

Define \textit{shift} 

This is trivial; it's not even recursive!

\[
\begin{align*}
\text{(define shift} \\
\quad \text{(lambda} (\text{pair}) \\
\quad \quad \text{(build} (\text{first} (\text{first} \text{pair})) \\
\quad \quad \quad \text{(build} (\text{second} (\text{first} \text{pair})) \\
\quad \quad \quad \quad \text{(second} \text{pair})))))
\end{align*}
\]

Describe what \textit{shift} does.

Here are our words:

"The function \textit{shift} takes a pair whose first component is a pair and builds a pair by shifting the second part of the first component into the second component."

Now look at this function:

Both functions change their arguments for their recursive uses but in neither case is the change guaranteed to get us closer to the goal.

\[
\begin{align*}
\text{(define align} \\
\quad \text{(lambda} (\text{pora}) \\
\quad \quad \text{(cond} \\
\quad \quad \quad ((\text{atom?} \text{pora}) \text{pora}) \\
\quad \quad \quad ((\text{a-pair?} (\text{first} \text{pora})) \\
\quad \quad \quad \quad (\text{align} (\text{shift} \text{pora})) \\
\quad \quad \quad \quad (\text{else} (\text{build} (\text{first} \text{pora}) \\
\quad \quad \quad \quad \quad (\text{align} (\text{second} \text{pora}))))))))
\end{align*}
\]

What does it have in common with \textit{keep-looking}?

In the second \texttt{cond-line} \textit{shift} creates an argument for \textit{align} that is not a part of the original argument.

Why are we not guaranteed that \textit{align} makes progress?

The Seventh Commandment.
<table>
<thead>
<tr>
<th>Question</th>
<th>Answer</th>
</tr>
</thead>
<tbody>
<tr>
<td>Is the new argument at least smaller than the original one?</td>
<td>It does not look that way.</td>
</tr>
<tr>
<td>Why not?</td>
<td>The function <em>shift</em> only rearranges the pair it gets.</td>
</tr>
<tr>
<td>And?</td>
<td>Both the result and the argument of <em>shift</em> have the same number of atoms.</td>
</tr>
<tr>
<td>Can you write a function that counts the number of atoms in <em>align</em>'s arguments?</td>
<td>No problem:</td>
</tr>
<tr>
<td></td>
<td>(define <em>length</em></td>
</tr>
<tr>
<td></td>
<td>(lambda (pora)</td>
</tr>
<tr>
<td></td>
<td>(cond</td>
</tr>
<tr>
<td></td>
<td>((atom? pora) 1)</td>
</tr>
<tr>
<td></td>
<td>(else</td>
</tr>
<tr>
<td></td>
<td>(+ (<em>length</em> (first pora))</td>
</tr>
<tr>
<td></td>
<td>(<em>length</em> (second pora))))))</td>
</tr>
<tr>
<td>Is <em>align</em> a partial function?</td>
<td>We don’t know yet. There may be arguments for which it keeps aligning things.</td>
</tr>
<tr>
<td>Is there something else that changes about the arguments to <em>align</em> and its recursive uses?</td>
<td>Yes, there is. The first component of a pair becomes simpler, though the second component becomes more complicated.</td>
</tr>
<tr>
<td>In what way is the first component simpler?</td>
<td>It is only a part of the original pair's first component.</td>
</tr>
<tr>
<td>Doesn’t this mean that <em>length</em> is the wrong function for determining the length of the argument? Can you find a better function?</td>
<td>A better function should pay more attention to the first component.</td>
</tr>
<tr>
<td>How much more attention should we pay to the first component?</td>
<td>At least twice as much.</td>
</tr>
</tbody>
</table>

... and Again, and Again, and Again, ...
Do you mean something like \textit{weight}^* \text{?} \hspace{1cm} \text{That looks right.}

\begin{verbatim}
(define weight* 
  (lambda (pora) 
    (cond 
      ((atom? pora) 1) 
      (else 
        (+ (* (weight* (first pora)) 2) 
            (weight* (second pora))))))
\end{verbatim}

What is \((\text{weight}* x)\) where 
\(x = ((a \ b \ c))\) \hspace{1cm} 7.

And what is \((\text{weight}* x)\) where 
\(x = (a \ (b \ c))\) \hspace{1cm} 5.

Does this mean that the arguments get simpler? \hspace{1cm} Yes, the weight*’s of align’s arguments become successively smaller.

Is align a partial function? \hspace{1cm} No, it yields a value for every argument.

Here is \textit{shuffle} which is like align but uses \textit{revpair} from chapter 7, instead of \textit{shift}: \hspace{1cm} The functions \textit{shuffle} and \textit{revpair} swap the components of pairs when the first component is a pair.

\begin{verbatim}
(define shuffle 
  (lambda (pora) 
    (cond 
      ((atom? pora) pora) 
      ((a-pair? (first pora)) 
        (shuffle (revpair pora))) 
      (else 
        (build (first pora) 
               (shuffle (second pora))))))
\end{verbatim}

Does this mean that \textit{shuffle} is total? \hspace{1cm} We don’t know.
Let's try it. What is the value of \((\text{shuffle } x)\) where 
\(x\) is \((\text{a (b c)})\).

\((\text{shuffle } x)\)
where 
\(x\) is \((\text{a b})\)

Okay, let's try something interesting. What is the value of \((\text{shuffle } x)\) where 
\(x\) is \(((\text{a b}) \ (\text{c d}))\)  

And how are we going to do that?  
We are going to determine the value of 
\((\text{shuffle } \text{pora})\) where \(\text{pora}\) is \(((\text{c d}) \ (\text{a b}))\).

Doesn't this mean that we need to know the value of \((\text{shuffle } \text{revpair } \text{pora}))\) where 
\(\text{revpair } \text{pora}\) is \(((\text{a b}) \ (\text{c d}))\)

And?  
The function \text{shuffle} is not total because it now swaps the components of the pair again, 
which means that we start all over.

Is this function total?  
It doesn’t yield a value for 0, but otherwise nobody knows. Thank you, Lothar Collatz (1910–1990).
What is the value of \((A\ 1\ 0)\)

2.

\((A\ 1\ 1)\)

3.

\((A\ 2\ 2)\)

7.

Here is the definition of \(A\)

\[
\text{(define } A \text{ (lambda } (n\ m) \text{ (cond ((zero? } n) \text{ (add1 } m)) ((zero? } m) \text{ (A (sub1 } n) 1)) (else (A (sub1 } n) (A n (sub1 } m))))))))
\]

What does \(A\) have in common with \(\text{shuffle}\) and \(\text{looking}\)

A’s arguments, like \(\text{shuffle}’\)s and \(\text{looking}’\)s, do not necessarily decrease for the recursion.

How about an example?

That’s easy: \((A\ 1\ 2)\) needs the value of \((A\ 0\ (A\ 1\ 1))\). And that means we need the value of \((A\ 0\ 3)\).

Does \(A\) always give an answer?

Yes, it is total.

Then what is \((A\ 4\ 3)\)

For all practical purposes, there is no answer.

What does that mean?

The page that you are reading now will have decayed long before we could possibly have calculated the value of \((A\ 4\ 3)\).

Thank you, Wilhelm Ackermann (1853–1946).

\[\text{But answer came there none—}
\text{And this was scarcely odd, because}
\text{They’d eaten every one.}
\]

The Walrus and The Carpenter

—Lewis Carroll
Wouldn’t it be great if we could write a function that tells us whether some function returns with a value for every argument? It sure would. Now that we have seen functions that never return a value or return a value so late that it is too late, we should have some tool like this around.

Okay, let’s write it. It sounds complicated. A function can work for many different arguments.

Then let’s make it simpler. For a warm-up exercise, let’s focus on a function that checks whether some function stops for just the empty list, the simplest of all arguments. That would simplify it a lot.

Here is the beginning of this function:

\[
(\text{define } \text{will-stop}\? \\
(\text{lambda } (f) \\
...))
\]

Can you fill in the dots?

Does \text{will-stop}\? return a value for all arguments? That’s the easy part: we said that it either returns \#t or \#f, depending on whether the argument stops when applied to ().

Is \text{will-stop}\? total then? Yes, it is. It always returns \#t or \#f.

Then let’s make up some examples. Here is the first one. What is the value of \(\text{will-stop}\? f\) where \(f\) is \text{length}\?

We know that \((\text{length } l)\) is 0 where \(l\) is ()

So? Then the value of \((\text{will-stop}\? \text{length})\) should be \#t.
Absolutely. How about another example? What is the value of \((\text{will-stop? eternity})\) \((\text{eternity (quote ())})\) doesn’t return a value. We just saw that.

Does this mean the value of \((\text{will-stop? eternity})\) is \#f

Yes, it does.

Do we need more examples?

Perhaps we should do one more example.

Okay, here is a function that could be an interesting argument for \text{will-stop?}

What does it do?

\begin{verbatim}
(define last-try
  (lambda (x)
    (and (will-stop? last-try)
         (eternity x))))
\end{verbatim}

What is \((\text{will-stop? last-try})\)

If we want the value of \((\text{last-try (quote ())})\), we must determine the value of
\((\text{and (will-stop? last-try)}
           \text{ (eternity (quote ()))))\).

We need to test it on ()

That depends on the value of \((\text{will-stop? last-try})\).

What is the value of
\((\text{and (will-stop? last-try)}
           \text{ (eternity (quote ()))))\)

Okay, then \((\text{and \#f (eternity (quote ()))))\), is \#f, since \((\text{and \#f \ldots})\) is always \#f.

There are only two possibilities. Let’s say
\((\text{will-stop? last-try})\) is \#f

Yes, it did.

So \((\text{last-try (quote ())})\) stopped, right?

But didn’t \text{will-stop?} predict just the opposite?

Yes, it did. We said that the value of
\((\text{will-stop? last-try})\) was \#f, which really means that \text{last-try} will not stop.

Chapter 9
So we must have been wrong about \((\text{will-stop? } \text{last-try})\)  
That’s correct. It must return \#t\, because \text{will-stop?} \ always gives an answer. We said it was total.

| Fine. If \((\text{will-stop? } \text{last-try})\) is \#t  
what is the value of \((\text{last-try } (\text{quote }()))\) | Now we just need to determine the value of \((\text{and } \#t (\text{eternity } (\text{quote }())))\), which is the same as the value of \((\text{eternity } (\text{quote }())))\). |
| What is the value of \((\text{eternity } (\text{quote }()))\) | It doesn’t have a value. We know that it doesn’t stop. |
| But that means we were wrong again! | True, since this time we said that \((\text{will-stop? } \text{last-try})\) was \#t\,. |
| What do you think this means? | Here is our meaning: “We took a really close look at the two possible cases. If we can \text{define} \text{will-stop?}, then  
\((\text{will-stop? } \text{last-try})\)  
must yield either \#t or \#f. But it cannot—due to the very definition of what \text{will-stop?} \ is supposed to do. This must mean that \text{will-stop?} cannot be \text{defined}.” |
| Is this unique? | Yes, it is. It makes \text{will-stop?} the first function that we can describe precisely but cannot \text{define} in our language. |
| Is there any way around this problem? | No. Thank you,  
Alan M. Turing (1912–1954)  
and  
| What is \((\text{define } \ldots)\) | This is an interesting question. We just saw that \((\text{define } \ldots)\) doesn’t work for \text{will-stop?}. |

... and Again, and Again, and Again, ...
So what are recursive definitions?

Hold tight, take a deep breath, and plunge forward when you're ready.

Is this the function \texttt{length}?

\begin{verbatim}
(define length
  (lambda (l)
    (cond
      ((null? l) 0)
      (else (add1 (length (cdr l)))))))
\end{verbatim}

It sure is.

What if we didn't have \texttt{(define ...)} anymore? Could we still define \texttt{length}?

Without \texttt{(define ...)} nothing, and especially not the body of \texttt{length}, could refer to \texttt{length}.

What does this function do?

\begin{verbatim}
(lambdas (l)
  (cond
    ((null? l) 0)
    (else (add1 (eternity (cdr l))))))
\end{verbatim}

It determines the length of the empty list and nothing else.

What happens when we use it on a non-empty list?

No answer. If we give \texttt{eternity} an argument, it gives no answer.

What does it mean for this function that looks like \texttt{length}?

It just won't give any answer for non-empty lists.

Suppose we could name this new function. What would be a good name?

\begin{itemize}
  \item \texttt{length}_0 because the function can only determine the length of the empty list.
\end{itemize}

How would you write a function that determines the length of lists that contain one or fewer items?

Well, we could try the following.

\begin{verbatim}
(lambda (l)
  (cond
    ((null? l) 0)
    (else (add1 (length_0 (cdr l))))))
\end{verbatim}
Almost, but (define ...) doesn’t work for \textit{length}_0

So, replace \textit{length}_0 by its definition.

\begin{verbatim}
(lambda (l)
 (cond
   ((null? l) 0)
   (else
    (add1
      ((lambda (l)
         (cond
           ((null? l) 0)
           (else (add1
                  (eternity (cdr l))))))
      (cdr l))))
\end{verbatim}

And what’s a good name for this function?

That’s easy: \textit{length}_\leq 1.

Is this the function that would determine the lengths of lists that contain two or fewer items?

Yes, this is \textit{length}_\leq 2. We just replace \textit{eternity} with the next version of \textit{length}.

Now, what do you think recursion is?

What do you mean?

\begin{verbatim}
(lambda (l)
 (cond
   ((null? l) 0)
   (else
    (add1
      ((lambda (l)
         (cond
           ((null? l) 0)
           (else (add1
                  (eternity (cdr l))))))
      (cdr l))))
\end{verbatim}

\ldots and \textit{Again, and Again, and Again}, \ldots
Well, we have seen how to determine the length of a list with no items, with no more than one item, with no more than two items, and so on. How could we get the function \textit{length} back?

\begin{verbatim}
((lambda (length)
   (lambda (l)
     (cond
       ((null? l) 0)
       (else (add1 (length (cdr l)))))))
eternity)
\end{verbatim}

If we could write an infinite function in the style of \textit{length}_0, \textit{length}_{\leq 1}, \textit{length}_{\leq 2}, \ldots, then we could write \textit{length}_\infty, which would determine the length of all lists that we can make.

How long are the lists that we can make?

Well, a list is either empty, or it contains one element, or two elements, or three, or four, \ldots, or 1001, \ldots

But we can't write an infinite function.

No, we can't.

And we still have all these repetitions and patterns in these functions.

Yes, we do.

What do these patterns look like?

All these programs contain a function that looks like \textit{length}. Perhaps we should abstract out this function: see The Ninth Commandment.

Let's do it!

We need a function that looks just like \textit{length} but starts with (\texttt{lambda} \textit{length} \ldots).

Do you mean this?

Yes, that's okay. It creates \textit{length}_0.
Rewrite $length_{\leq 1}$ in the same style.

$((\text{lambda} (f)\
   \text{lambda} (l)\
   \text{cond}\
   ((\text{null?} \ l) 0)\n   (\text{else} (\text{add1} (f \ (\text{cdr} \ l)))))))$

$$((\text{lambda} (g)\
   \text{lambda} (l)\
   \text{cond}\
   ((\text{null?} \ l) 0)\n   (\text{else} (\text{add1} (g \ (\text{cdr} \ l))))))$$

Do we have to use $length$ to name the argument?

No, we just used $f$ and $g$. As long as we are consistent, everything's okay.

How about $length_{\leq 2}$

$((\text{lambda} (lengt h)\
   \text{lambda} (l)\
   \text{cond}\
   ((\text{null?} \ l) 0)\n   (\text{else} (\text{add1} (\text{length} \ (\text{cdr} \ l))))))$

$$((\text{lambda} (length)\
   \text{lambda} (l)\
   \text{cond}\
   ((\text{null?} \ l) 0)\n   (\text{else} (\text{add1} (\text{length} \ (\text{cdr} \ l))))))$$

Close, but there are still repetitions.

True. Let's get rid of them.

Where should we start?

Name the function that takes $length$ as an argument and that returns a function that looks like $length$. 

... and Again, and Again, and Again, ...
<table>
<thead>
<tr>
<th>What’s a good name for this function?</th>
<th>How about \textit{mk-length} for “make length”?</th>
</tr>
</thead>
<tbody>
<tr>
<td>Okay, do this to $\text{length}_0$</td>
<td>No problem.</td>
</tr>
<tr>
<td>Is this $\text{length}_{\leq 1}$</td>
<td>It sure is. And this is $\text{length}_{\leq 2}$.</td>
</tr>
<tr>
<td>Can you write $\text{length}_{\leq 3}$ in this style?</td>
<td>Sure. Here it is.</td>
</tr>
<tr>
<td>What is recursion like?</td>
<td>It is like an infinite tower of applications of \textit{mk-length} to an arbitrary function.</td>
</tr>
</tbody>
</table>

$$\begin{align*}
\text{length}_0 & \equiv \begin{array}{l}
\text{(lambda \ (mk-length)} \\
\text{\quad (mk-length eternity))} \\
\text{(lambda \ (length)} \\
\text{\quad (lambda \ (l)} \\
\text{\quad \quad (cond)} \\
\text{\quad \quad \quad ((null? \ l) 0)} \\
\text{\quad \quad \quad (else \ (add1 \ (length \ (cdr \ l))))))))
\end{array}
\end{align*}$$

$$\begin{align*}
\text{length}_{\leq 1} & \equiv \begin{array}{l}

\text{\quad (mk-length)} \\
\text{\quad \quad (mk-length eternity))} \\
\text{(lambda \ (length)} \\
\text{\quad (lambda \ (l)} \\
\text{\quad \quad \quad (cond)} \\
\text{\quad \quad \quad \quad ((null? \ l) 0)} \\
\text{\quad \quad \quad \quad (else \ (add1 \ (length \ (cdr \ l))))))))
\end{array}
\end{align*}$$

$$\begin{align*}
\text{length}_{\leq 3} & \equiv \begin{array}{l}
\text{(lambda \ (mk-length)} \\
\text{\quad (mk-length)} \\
\text{\quad \quad (mk-length)} \\
\text{\quad \quad \quad (mk-length eternity))} \\
\text{\quad (lambda \ (length)} \\
\text{\quad \quad (lambda \ (l)} \\
\text{\quad \quad \quad \quad \quad (cond)} \\
\text{\quad \quad \quad \quad \quad \quad ((null? \ l) 0)} \\
\text{\quad \quad \quad \quad \quad \quad (else \ (add1 \ (length \ (cdr \ l))))))))
\end{array}
\end{align*}$$

164  
Chapter 9
Do we really need an infinite tower?  

Not really of course. Everytime we use \textit{length} we only need a finite number, but we never know how many.

Could we guess how many we need?  

Sure, but we may not guess a large enough number.

When do we find out that we didn't guess a large enough number?  

When we apply the function \textit{eternity} that is passed to the innermost \textit{mk-length}.

What if we could create another application of \textit{mk-length} to \textit{eternity} at this point?  

That would only postpone the problem by one, and besides, how could we do that?

Well, since nobody cares what function we pass to \textit{mk-length} we could pass it \textit{mk-length} initially.  

That's the right idea. And then we invoke \textit{mk-length} on \textit{eternity} and the result of this on the \textit{cdr} so that we get one more piece of the tower.

Then is this still \textit{length}\textsubscript{0}\?  

\begin{verbatim}
(((lambda (mk-length)
       (mk-length mk-length))
  (lambda (length)
    (lambda (l)
      (cond
        ((null? l) 0)
        (else (add1
          (length (cdr l))))))))
\end{verbatim}

Yes, we could even use \textit{mk-length} instead of \textit{length}.  

\begin{verbatim}
(((lambda (mk-length)
       (mk-length mk-length))
  (lambda (mk-length)
    (lambda (l)
      (cond
        ((null? l) 0)
        (else (add1
          (mk-length (cdr l)))))
\end{verbatim}

Why would we want to do that?  

All names are equal, but some names are more equal than others.\textsuperscript{1}

\textsuperscript{1} With apologies to George Orwell (1903-1950).
True: as long as we use the names consistently, we are just fine.

And \textit{mk-length} is a far more equal name than \textit{length}. If we use a name like \textit{mk-length}, it is a constant reminder that the first argument to \textit{mk-length} is \textit{mk-length}.

Now that \textit{mk-length} is passed to \textit{mk-length} can we use the argument to create an additional recursive use?

Yes, when we apply \textit{mk-length} once, we get \textit{length}_{\leq 1}

\[
((\lambda (\textit{mk-length})
  (\textit{mk-length} \textit{mk-length}))
 (\lambda (\textit{mk-length})
  (\lambda (l)
   (\text{cond}
     ((\text{null?} l) 0)
     (\text{else} (\text{add1}
       ((\textit{mk-length} \textit{eternity})
        (\textit{cdr} l))))))))
\]

What is the value of

\[
(((\lambda (\textit{mk-length})
  (\textit{mk-length} \textit{mk-length}))
 (\lambda (\textit{mk-length})
  (\lambda (l)
   (\text{cond}
     ((\text{null?} l) 0)
     (\text{else} (\text{add1}
       ((\textit{mk-length} \textit{eternity})
        (\textit{cdr} l))))))))
\]

This is a good exercise. Work it out with paper and pencil.

Could we do this more than once?

Yes, just keep passing \textit{mk-length} to itself, and we can do this as often as we need to!
What would you call this function?  

It is length, of course.

```
((lambda (mk-length)
    (mk-length mk-length))
 (lambda (mk-length)
    (lambda (l)
      (cond
        ((null? l) 0)
        (else (add1
            ((mk-length mk-length)
              (cdr l))))))))
```

How does it work?  

It keeps adding recursive uses by passing mk-length to itself, just as it is about to expire.

One problem is left: it no longer contains the function that looks like length  

We could extract this new application of mk-length to itself and call it length.

```
((lambda (mk-length)
    (mk-length mk-length))
 (lambda (mk-length)
    (lambda (l)
      (cond
        ((null? l) 0)
        (else (add1
            ((mk-length mk-length)
              (cdr l)))))))))
```

Can you fix that?

Why?  

Because it really makes the function length.
How about this?

```lisp
((lambda (mk-length)
    (mk-length mk-length))
 (lambda (mk-length)
    ((lambda (length)
        (lambda (l)
            (cond
                ((null? l) 0)
                (else (add1 (length (cdr l)))))))))
 (mk-length mk-length)))
```

Yes, this looks just fine.

Let's see whether it works. Okay.

What is the value of

```lisp
(((lambda (mk-length)
    (mk-length mk-length))
 (lambda (mk-length)
    ((lambda (length)
        (lambda (l)
            (cond
                ((null? l) 0)
                (else (add1 (length (cdr l)))))))))
 (mk-length mk-length)))
```

It should be 1.

That's true, because the value of this expression is the function that we need to apply to `l` where

`l` is `(apples)`
So we really need the value of

\[
((\text{lambda } (\text{mk-length}))
  ((\text{lambda } (\text{length}))
    (\text{lambda } (l))
    (\text{cond}
      ((\text{null? } l) 0)
      (\text{else} \ (\text{add1 } (\text{length } (\text{cdr } l))))))
  (\text{mk-length } \text{mk-length}))
\]

But then we really need to know the value of

\[
((\text{lambda } (\text{length}))
  (\text{lambda } (l))
  (\text{cond}
    ((\text{null? } l) 0)
    (\text{else} \ (\text{add1 } (\text{length } (\text{cdr } l))))))
\]

\[
((\text{lambda } (\text{mk-length}))
  ((\text{lambda } (\text{length}))
    (\text{lambda } (l))
    (\text{cond}
      ((\text{null? } l) 0)
      (\text{else} \ (\text{add1 } (\text{length } (\text{cdr } l))))))
  (\text{mk-length } \text{mk-length}))
\]

\[
(\text{mk-length } \text{mk-length})
\]

\[
(\text{null? } l) 0)
(\text{else} \ (\text{add1 } (\text{length } (\text{cdr } l))))))
\]

\[
(\text{mk-length } \text{mk-length}))
\]

... and Again, and Again, and Again, ...
Yes, there is no end to it. Why? Because we just keep applying \( mk\text{-length} \) to itself again and again and again . . .

Is this strange? It is because \( mk\text{-length} \) used to return a function when we applied it to an argument. Indeed, it didn’t matter what we applied it to.

But now that we have extracted
\[
(mk\text{-length} \ mk\text{-length})
\]
from the function that makes \( length \)
it does not return a function anymore.

Turn the application of \( mk\text{-length} \) to itself in our last correct version of \( length \) into a function:

\[
((\text{lambda} \ (mk\text{-length})
\quad (mk\text{-length} \ mk\text{-length}))
\quad (\text{lambda} \ (mk\text{-length})
\quad (\text{lambda} \ (l)
\quad (\text{cond}
\quad ((\text{null?} \ l) \ 0)
\quad (\text{else} \ (\text{add1}
\quad ((mk\text{-length} \ mk\text{-length})
\quad (\text{cdr} \ l)))))))
\]

How?

Here is a different way. If \( f \) is a function of one argument, is \((\text{lambda} \ (x) \ (f \ x))\) a function of one argument?

Yes, it is.

If \((mk\text{-length} \ mk\text{-length})\) returns a function of one argument, does \((\text{lambda} \ (x)
\quad ((mk\text{-length} \ mk\text{-length}) \ x))\) return a function of one argument?

Actually,
\[
(\text{lambda} \ (x)
\quad ((mk\text{-length} \ mk\text{-length}) \ x))
\]
is a function!
Okay, let’s do this to the application of \textit{mk-length} to itself.

\[
\begin{align*}
\text{(lambda (mk-length)} \\
\text{  (mk-length mk-length))} \\
\text{(lambda (mk-length)}} \\
\text{  (lambda (l))} \\
\text{  (cond} \\
\text{    ((null? l) 0)} \\
\text{    (else} \\
\text{      (add1} \\
\text{        (lambda (x)} \\
\text{          ((mk-length mk-length) x))} \\
\text{        (cdr l))))) }) \\
\text{  (lambda (x))} \\
\text{    ((mk-length mk-length) x)))}
\end{align*}
\]

Move out the new function so that we get \textit{length} back.

\[
\begin{align*}
\text{(lambda (mk-length)} \\
\text{  (mk-length mk-length))} \\
\text{(lambda (mk-length)}} \\
\text{  (lambda (length)}} \\
\text{    (lambda (l))} \\
\text{    (cond} \\
\text{      ((null? l) 0)} \\
\text{      (else} \\
\text{        (add1 (length (cdr l)))))}) \\
\text{  (lambda (x))} \\
\text{    ((mk-length mk-length) x)))}
\end{align*}
\]

Is it okay to move out the function? Yes, we just always did the opposite by replacing a name with its value. Here we extract a value and give it a name.

Can we extract the function in the box that looks like \textit{length} and give it a name? Yes, it does not depend on \textit{mk-length} at all!
Is this the right function? Yes.

(((lambda (le)
  ((lambda (mk-length)
    (mk-length mk-length)))
  (lambda (mk-length)
    (le (lambda (x)
      ((mk-length mk-length) x)))))))

What did we actually get back? We extracted the original function \( mk\text{-length} \).

Let's separate the function that makes \( length \) from the function that looks like \( length \). That's easy.

(((lambda (le)
  ((lambda (mk-length)
    (mk-length mk-length)))
  (lambda (mk-length)
    (le (lambda (x)
      ((mk-length mk-length) x)))))))

Does this function have a name? Yes, it is called the applicative-order \( Y \) combinator.

(define Y
  (lambda (le)
    ((lambda (f) (f f))
      (lambda (f)
        (le (lambda (x) ((f f) x)))))))

Does \( \text{define} \ldots \) work again? Sure, now that we know what recursion is.

Do you now know why \( Y \) works? Read this chapter just one more time and you will.

---

*Stop the World—I Want to Get Off.*
Leslie Bricusse and Anthony Newley

... and Again, and Again, and Again, ...
10.
What Is the Value of All of This?
An entry is a pair of lists whose first list is a set. Also, the two lists must be of equal length. Make up some examples for entries.

Here are our examples:

- ((appetizer entrée beverage)
  (pâté boeuf vin))
  
- ((appetizer entrée beverage)
  (beer beer beer))
  
- ((beverage dessert)
  ((food is) (number one with us))).

How can we build an entry from a set of names and a list of values?

(define new-entry build)

Try to build our examples with this function.

What is `(lookup-in-entry name entry)` where `name` is entrée and `entry` is ((appetizer entrée beverage)
(food tastes good))

tastes.

What if `name` is dessert

In this case we would like to leave the decision about what to do with the user of `lookup-in-entry`.

How can we accomplish this?

`lookup-in-entry` takes an additional argument that is invoked when `name` is not found in the first list of an entry.

How many arguments do you think this extra function should take?

We think it should take one, `name`. Why?
Here is our definition of \textit{lookup-in-entry}

\begin{verbatim}
(define lookup-in-entry
  (lambda (name entry entry-f)
    (lookup-in-entry-help name
      (first entry)
      (second entry)
      entry-f))))
\end{verbatim}

Finish the function \textit{lookup-in-entry-help}

\begin{verbatim}
(define lookup-in-entry-help
  (lambda (name names values entry-f)
    (cond
      ((null? names) (entry-/ name))
      ((eq? (car names) name)
        (car values))
      (else (lookup-in-entry-help name
                  (cdr names)
                  (cdr values)
                  entry-f))))
\end{verbatim}

A table (also called an environment) is a list of entries. Here is one example: the empty table, represented by ()
Make up some others.

Here is another one:

\begin{verbatim}
(((appetizer entrée beverage)
  (paté boeuf vin))
  ((beverage dessert)
    ((food is) (number one with us))))
\end{verbatim}

Define the function \textit{extend-table} which takes an entry and a table (possibly the empty one) and creates a new table by putting the new entry in front of the old table.

\begin{verbatim}
(define extend-table cons)
\end{verbatim}

What is \texttt{(lookup-in-table name table table-f)}
where
- \texttt{name} is entrée
- \texttt{table} is (((entrée dessert)
  (spaghetti spumoni))
  ((appetizer entrée beverage)
    (food tastes good)))

and
- \texttt{table-f} is (lambda (name) ...)

It could be either spaghetti or tastes, but \textit{lookup-in-table} searches the list of entries in order. So it is spaghetti.
Write `lookup-in-table`  
Hint: Don’t forget to get some help.

```
(define lookup-in-table
  (lambda (name table table-f)
    (cond
      ((null? table) (table-f name))
      (else (lookup-in-entry name (car table))
        (lambda (name)
          (lookup-in-table name (cdr table) table-f)))))
```

This function is the action to take when the name is not found in the first entry.

Can you describe what the following function represents:

```
(lambda (name)
  (lookup-in-table name
    (cdr table)
    table-f))
```

This function is the action to take when the name is not found in the first entry.

In the preface we mentioned that sans serif typeface would be used to represent atoms. To this point it has not mattered. Henceforth, you must notice whether or not an atom is in sans serif.

We hope so. This is “sans serif” in sans serif.

Did you notice that “sans serif” was not in sans serif?

We hope so. This is “sans serif” in sans serif.

Have we chosen a good representation for expressions?

Yes. They are all S-expressions so they can be data for functions.

What kind of functions?

For example, `value`.

Do you remember `value` from chapter 6?

Recall that `value` is the function that returns the natural value of expressions.

What is the value of `car (quote (a b c))`?

We don’t even know what `(quote (a b c))` is.

What Is the Value of All of This?
What is the value of 
\[
(\text{cons rep-a} \\
(\text{cons rep-b} \\
(\text{cons rep-c} \\
(\text{quote ())])))
\]
where 
- \text{rep-a} is a 
- \text{rep-b} is b 
and 
- \text{rep-c} is c 

It is the same as \((a\ b\ c)\).

Great. And what is the value of 
\[
(\text{cons rep-car} \\
(\text{cons (cons rep-quote} \\
(\text{cons rep-a} \\
(\text{cons rep-b} \\
(\text{cons rep-c} \\
(\text{quote ())}) \\
(\text{quote ())}) \\
(\text{quote ())}) \\
(\text{quote ())}) \\
(\text{quote ())}))
\]
where 
- \text{rep-car} is car 
- \text{rep-quote} is quote 
- \text{rep-a} is a 
- \text{rep-b} is b 
and 
- \text{rep-c} is c 

It is a representation of the expression: 
\((\text{car (quote (a b c))})\).

What is the value of 
\[(\text{car (quote (a b c))})\]

a.

What is \((\text{value e})\) 
where 
\(e\) is \((\text{car (quote (a b c))})\)

a.

What is \((\text{value e})\) 
where 
\(e\) is \((\text{quote (car (quote (a b c)))})\)

(car (quote (a b c))).
| What is \((\text{value } e)\) where \(e\) is \((\text{addl 6})\) | 7. |
| What is \((\text{value } e)\) where \(e\) is 6 | 6, because numbers are constants. |
| What is \((\text{value } e)\) where \(e\) is \((\text{quote nothing})\) | nothing. |
| What is \((\text{value } e)\) where \(e\) is nothing | nothing has no value. |
| What is \((\text{value } e)\) where \(e\) is \(((\text{lambda (nothing)}\ (\text{cons nothing (quote ()))))\) (quote (from nothing comes something))) | (from nothing comes something)). |
| What is \((\text{value } e)\) where \(e\) is \(((\text{lambda (nothing)}\ (\text{cond}\ \ (\text{nothing (quote something)})\ (\text{else (quote nothing)})))\) #t) | something. |
| What is the type of \(e\) where \(e\) is 6 | *const. |
| What is the type of \(e\) where \(e\) is \#f | *const. |

What Is the Value of All of This?
What is \((value\ e)\) where \(e\) is \(\#f\) \(#f\).

What is the type of \(e\) where \(e\) is cons \(*const.*\)

What is \((value\ e)\) where \(e\) is car (primitive car).

What is the type of \(e\) where \(e\) is (quote nothing) \(*quote.*\)

What is the type of \(e\) where \(e\) is nothing \(*identifier.*\)

What is the type of \(e\) where \(e\) is (lambda (x y) (cons x y)) \(*lambda.*\)

What is the type of \(e\) where \(e\) is ((lambda (nothing) (cond (nothing (quote something)) (else (quote nothing)))\) #t) \(*application.*\)

What is the type of \(e\) where \(e\) is (cond (nothing (quote something)) (else (quote nothing))) \(*cond.*\)
How many types do you think there are?

We found six:
- *const
- *quote
- *identifier
- *lambda
- *cond

and
- *application.

How do you think we should represent types?

We choose functions. We call these functions “actions.”

If actions are functions that do “the right thing” when applied to the appropriate type of expression, what should value do?

You guessed it. It would have to find out the type of expression it was passed and then use the associated action.

Do you remember atom-to-function from chapter 8?

We found atom-to-function useful when we rewrote value for numbered expressssions.

Below is a function that produces the correct action (or function) for each possible S-expression:

```
(define expression-to-action
  (lambda (e)
    (cond
      ((atom? e) (atom-to-action e))
      (else (list-to-action e))))
```

Define the function atom-to-action

```
(define atom-to-action
  (lambda (e)
    (cond
      ((number? e) *const)
      ((eq? e #t) *const)
      ((eq? e #f) *const)
      ((eq? e (quote cons)) *const)
      ((eq? e (quote car)) *const)
      ((eq? e (quote cdr)) *const)
      ((eq? e (quote null?)) *const)
      ((eq? e (quote eq?)) *const)
      ((eq? e (quote atom?)) *const)
      ((eq? e (quote zero?)) *const)
      ((eq? e (quote add1)) *const)
      ((eq? e (quote sub1)) *const)
      ((eq? e (quote number?)) *const)
      (else *identifier))))
```

---

1 Ill-formed S-expressions such as (quote a b), (), (lambda (#t) #t), (lambda (5) 5), (lambda (car) car), (lambda a), (cond (3 c) (else b) (6 a)), and (1 2) are not considered here. They can be detected by an appropriate function to which S-expressions are submitted before they are passed on to value.
Now define the help function \textit{list-to-action}

\begin{verbatim}
(define list-to-action
  (lambda (e)
    (cond
      ((atom? (car e))
        (cond
          ((eq? (car e) (quote quote))
            *quote)
          ((eq? (car e) (quote lambda))
            *lambda)
          ((eq? (car e) (quote cond))
            *cond)
          (else *application)))
      (else *application))))
\end{verbatim}

Assuming that \textit{expression-to-action} works, we can use it to define \textit{value} and \textit{meaning}

\begin{verbatim}
(define value
  (lambda (e)
    (meaning e (quote ()))))
\end{verbatim}

\begin{verbatim}
(define meaning
  (lambda (e table)
    ((expression-to-action e) e table)))
\end{verbatim}

What is \texttt{(quote ())} in the definition of \textit{value}\footnote{The function \textit{value} approximates the function \texttt{eval} available in Scheme (and Lisp).}

It is the empty table. The function \textit{value}, together with all the functions it uses, is called an interpreter.

Actions do speak louder than words.

How many arguments should actions take according to the above? Two, the expression \textit{e} and a table.
Here is the action for constants.

```scheme
(define *const
  (lambda (e table)
    (cond
      ((number? e) e)
      ((eq? e #t) #t)
      ((eq? e #f) #f)
      (else (build (quote primitive) e))))
```

Is it correct?

Here is the action for *quote

```scheme
(define *quote
  (lambda ((e table)
    (text-of e)))
```

Define the help function `text-of`

Have we used the table yet? No, but we will in a moment.

Why do we need the table? To remember the values of identifiers.

Given that the table contains the values of identifiers, write the action *identifier

```scheme
(define *identifier
  (lambda (e table)
    (lookup-in-table e table initial-table)))
```

Here is initial-table

```scheme
(define initial-table
  (lambda (name)
    (car (quote ()))))
```

When is it used?

What is the value of (lambda (x) x) We don’t know yet, but we know that it must be the representation of a non-primitive function.

What Is the Value of All of This?

Yes, for numbers, it just returns the expression, and this is all we have to do for 0, 1, 2, ... For #t, it returns true. For #f, it returns false. And all other atoms of constant type represent primitives.

(define text-of second)

(define *identifier
  (lambda (e table)
    (lookup-in-table e table initial-table)))

Let’s hope never. Why?
How are non-primitive functions different from primitives?

We know what primitives do; non-primitives are defined by their arguments and their function bodies.

So when we want to use a non-primitive we need to remember its formal arguments and its function body.

At least. Fortunately this is just the cdr of a lambda expression.

And what else do we need to remember?

We will also put the table in, just in case we might need it later.

And how do we represent this?

In a list, of course.

Here is the action *lambda

```scheme
(define *lambda
  (lambda (e table)
    (build (quote non-primitive)
      (cons table (cdr e))))))
```

What is (meaning e table) where

- `e` is (lambda (x) (cons x y))
- `table` is (((y z) ((8) 9)))

It is probably a good idea to define some help functions for getting back the parts in this three element list (i.e., the table, the formal arguments, and the body). Write table-of, formals-of, and body-of

```
(define table-of-first)
(define formals-of-second)
(define body-of-third)
```

Describe (cond ...) in your own words.

It is a special form that takes any number of cond-lines. It considers each line in turn. If the question part on the left is false, it looks at the rest of the lines. Otherwise it proceeds to answer the right part. If it sees an else-line, it treats that cond-line as if its question part were true.
Here is the function `evcon` that does what we just said in words:

```scheme
(define evcon
  (lambda (lines table)
    (cond
      ((else? (question-of (car lines)))
        (meaning (answer-of (car lines)) table))
      ((meaning (question-of (car lines)) table)
        (meaning (answer-of (car lines)) table))
      (else (evcon (cdr lines) table))))
```

Write `else?` and the help functions `question-of` and `answer-of`.

Didn’t we violate The First Commandment?

Yes, we don’t ask `(null? lines)`, so one of the questions in every `cond` better be true.

Now use the function `evcon` to write the `*cond` action.

```scheme
(define *cond
  (lambda (e table)
    (evcon (cond-lines-of e) table)))
```

Aren’t these help functions useful?

Yes, they make things quite a bit more readable. But you already knew that.

Do you understand `*cond` now?

Perhaps not.

How can you become familiar with it?

The best way is to try an example. A good one is:

```scheme
(*cond e table)
```

where

- `e` is `(cond (coffee klatsch) (else party))`
- `table` is `(((coffee) (#t)) ((klatsch party) (5 (6))))`.

What Is the Value of All of This?
<table>
<thead>
<tr>
<th>Question</th>
<th>Answer</th>
</tr>
</thead>
<tbody>
<tr>
<td>Have we seen how the table gets used?</td>
<td>Yes, *lambda and *identifier use it.</td>
</tr>
<tr>
<td>But how do the identifiers get into the table?</td>
<td>In the only action we have not defined: *application.</td>
</tr>
<tr>
<td>How is an application represented?</td>
<td>An application is a list of expressions whose car position contains an expression whose value is a function.</td>
</tr>
<tr>
<td>How does an application differ from a special form, like ( \text{and} \ldots, \text{or} \ldots ) or ( \text{cond} \ldots )?</td>
<td>An application must always determine the meaning of all its arguments.</td>
</tr>
<tr>
<td>Before we can apply a function, do we have to get the meaning of all of its arguments?</td>
<td>Yes.</td>
</tr>
</tbody>
</table>
| Write a function evlis that takes a list of (representations of) arguments and a table, and returns a list composed of the meaning of each argument. | (define evlis
   (lambda (args table)
     (cond
      ((null? args) (quote ()))
      (else
       (cons (meaning (car args) table)
             (evlis (cdr args) table)))))) |
| What else do we need before we can determine the meaning of an application? | We need to find out what its \text{function-of} means.                  |
| And what then?                                                         | Then we apply the meaning of the function to the meaning of the arguments. |
| Here is *application                                                  | Of course. We just have to define \text{apply}, \text{function-of}, and \text{arguments-of} correctly. |

(\text{define} *application
 (lambda (e table)
   (apply
    (meaning (function-of e) table)
    (evlis (arguments-of e) table))))

Is it correct?
Write function-of and arguments-of

(define function-of car)

(define arguments-of cdr)

How many different kinds of functions are there?

Two: primitives and non-primitives.

What are the two representations of functions?

(primitive primitive-name) and
(non-primitive (table formals body))

The list (table formals body) is called a closure record.

Write primitive? and non-primitive?

(define primitive? (lambda (l) (eq? (first l) (quote primitive))))

(define non-primitive? (lambda (l) (eq? (first l) (quote non-primitive))))

Now we can write the function apply

(define apply1 (lambda (fun vals) (cond
((primitive? fun) (apply-primitive (second fun) vals))
((non-primitive? fun) (apply-closure (second fun) vals))))

Here it is:

1 If fun does not evaluate to either a primitive or a non-primitive as in the expression ((lambda (x) (x 5)) 3), there is no answer. The function apply approximates the function apply available in Scheme (and Lisp).
This is the definition of `apply-primitive`

```
(define apply-primitive
  (lambda (name vals)
    (cond
      ((eq? name 1)
       (cons (first vals) (second vals)))
      ((eq? name (quote car))
       (car (first vals)))
      ((eq? name (quote cdr))
       (2 (first vals)))
      ((eq? name (quote null?))
       (null? (first vals)))
      ((eq? name (quote eq?))
       (3 (first vals) 4))
      ((eq? name (quote atom?))
       (5 (first vals)))
      ((eq? name (quote zero?))
       (zero? (first vals)))
      ((eq? name (quote add1))
       (add1 (first vals)))
      ((eq? name (quote sub1))
       (sub1 (first vals)))
      ((eq? name (quote number?))
       (number? (first vals))))
    )))
```

Fill in the blanks.

1. (quote cons)
2. cdr
3. eq?
4. (second vals)
5. :atom?

1 The function `apply-primitive` could check for applications of `cdr` to the empty list or `sub1` to 0, etc.

---

Is `apply-closure` the only function left? Yes, and `apply-closure` must extend the table.

How could we find the result of `(f a b)` where
- `f` is `(lambda (x y) (cons x y))`
- `a` is 1
- `b` is (2)

That's tricky. But we know what to do to find the meaning of
- `(cons x y)`

where `table` is `(((x y)
              (1 (2))))`.

Why can we do this? Here, we don't need `apply-closure`.

---

188 Chapter 10
Can you generalize the last two steps?

Applying a non-primitive function—a closure—to a list of values is the same as finding the meaning of the closure’s body with its table extended by an entry of the form

\[(\text{formals values})\]

In this entry, \textit{formals} is the \textit{formals} of the closure and \textit{values} is the result of \textit{evlis}.

Have you followed all this?

If not, here is the definition of \textit{apply-closure}.

\[
\begin{align*}
&\text{apply-closure} \\
&(\text{lambda} (\text{closure} \ \text{vals}) \\
&(\text{meaning} \ (\text{body-of closure}) \\
&(\text{extend-table} \\
&(\text{new-entry} \\
&(\text{formals-of closure}) \\
&\text{vals}) \\
&(\text{table-of closure})))))
\end{align*}
\]

This is a complicated function and it deserves an example.

In the following, \textit{closure} is ((((((u v w) \\
(1 2 3)) \\
((x y z) \\
(4 5 6))) \\
(x y) \\
(cons z x))

and

\textit{vals} is ((a b c) (d e f)).

What will be the new arguments of \textit{meaning}

The new \textit{e} for \textit{meaning} will be (cons z x) and the new \textit{table} for \textit{meaning} will be

\[
\begin{align*}
&(\text{new e}) \\
&(\text{new table}) \\
&((x y) \\
&((a b c) (d e f)) \\
&((u v w) \\
&(1 2 3)) \\
&((x y z) \\
&(4 5 6)))
\end{align*}
\]
What is the meaning of \((\text{cons } z \ x)\)
where \(z\) is 6
and
\(x\) is \((a\ b\ c)\)

The same as
\((\text{meaning } e \ \text{table})\)
where
\(e\) is \((\text{cons } z \ x)\)
and
\(table\) is
\[
((x\ y)
  
  ((a\ b\ c) (d\ e\ f))
  ((u\ v\ w)
    (1\ 2\ 3))
  ((x\ y\ z)
    (4\ 5\ 6)))
\]

Let's find the meaning of all the arguments.
What is
\((\text{evlis } \text{args } \text{table})\)
where
\(\text{args}\) is \((z\ x)\)
and
\(\text{table}\) is
\[
((x\ y)
  
  ((a\ b\ c) (d\ e\ f))
  ((u\ v\ w)
    (1\ 2\ 3))
  ((x\ y\ z)
    (4\ 5\ 6)))
\]

In order to do this, we must find both
\((\text{meaning } e \ \text{table})\)
where
\(e\) is \(z\)
and
\((\text{meaning } e \ \text{table})\)
where
\(e\) is \(x\).

What is the \((\text{meaning } e \ \text{table})\)
where \(e\) is \(z\)

6, by using *identifier.

What is \((\text{meaning } e \ \text{table})\)
where \(e\) is \(x\)

\((a\ b\ c)\), by using *identifier.

So, what is the result of \text{evlis}\n
\((6\ (a\ b\ c))\), because \text{evlis} returns a list of the meanings.

What is \((\text{meaning } e \ \text{table})\)
where \(e\) is \text{cons}

\((\text{primitive cons})\), by using *const.
We are now ready to \((\text{apply } \text{fun } \text{vals})\)
where
\(\text{fun}\) is \((\text{primitive cons})\)
and
\(\text{vals}\) is \((6 \ (a \ b \ c))\)
Which path should we take?

| Which cond-line is chosen for \((\text{apply-
} \text{primitive } \text{name } \text{vals})\) where \(\text{name}\) is \(\text{cons}\) and \(\text{vals}\) is \((6 \ (a \ b \ c))\) | The third:
\[
((\text{eq? } \text{name } (\textquote \text{cons}))\\
(\text{cons } (\text{first } \text{vals}) (\text{second } \text{vals}))).
\]

Are we finished now? Yes, we are exhausted.

But what about \((\text{define } \ldots)\) It isn’t needed because recursion can be obtained from the Y combinator.

Is \((\text{define } \ldots)\) really not needed? Yes, but see \textit{The Seasoned Schemer}.

Does that mean we can run the interpreter on the interpreter if we do the transformation with the Y combinator? Yes, but don’t bother.

What makes \textit{value} unusual? It sees representations of expressions.

Should \textit{will-stop}? see representations of expressions? That may help a lot.

Does it help? No, don’t bother—we can play the same game again. We would be able to define a function like \textit{last-try}? that will show that we cannot \textit{define} the new and improved \textit{will-stop}?

else Yes, it’s time for a banquet.

\textit{What Is the Value of All of This?}
You've reached the intermission. What are your options? You could quickly run out and get the rest of the show, *The Seasoned Schemer,* or you could read some of the books that we mention below. All of these books are classics and some of them are quite old; nevertheless they have stood the test of time and are all worthy of your notice. Some have nothing whatsoever to do with mathematics or logic, some have to do with mathematics, but only by way of telling an interesting story, and still others are just worth discovering. There should be no confusion: these books are not here to prepare you to read the sequel, they are just for your entertainment. At the end of *The Seasoned Schemer* you can find a set of references to Scheme and the reference to Common Lisp. Do not feel obliged to jump ahead to the next book. Take some time off and read some of these books instead. Then, when you have relaxed a bit, perhaps removed some of the calories that were foisted upon you, go ahead and dive into the sequel. Enjoy!
